# Introduction

These protocols have been developed to measure resource savings, including electric energy capacity, natural gas, and other resource savings, and to measure electric energy and capacity from renewable energy and distributed generation systems. -Specific protocols for determination of the resource savings or generation from each program are presented for each eligible measure and technology.

These protocols use measured and customer data as input values in industry-accepted algorithms.- The data and input values for the algorithms come from the program application forms or from standard values. -The standard input values are based on the recent impact evaluations and best available measured or industry data applicable for the New Jersey programs when impact evaluations are not available.

# Purpose

These protocols were developed for the purpose of determining energy and resource savings for technologies and measures supported by New Jersey's Clean Energy Program. -The protocols will be updated from time to time to reflect the addition of new programs, modifications to existing programs, and the results of future program evaluations. -The protocols will be used consistently statewide to assess program impacts and calculate energy and resource savings to:

- 1. Report to the Board on program performance
- 2. Provide inputs for planning and cost-effectiveness calculations
- 3. Provide information to regulators and program administrators for determining eligibility for administrative performance incentives (to the extent that such incentives are approved by the BPU)
- 4. Assess the environmental benefits of program implementation

Resource savings to be measured include electric energy (kWh) and capacity (kW) savings, natural gas savings (therms), and savings of other resources (oil, propane, water, and maintenance), where applicable. In turn, these resource savings will be used to determine avoided environmental emissions.- The Protocols are also utilized to support preliminary estimates of the electric energy and capacity from renewable energy and distributed generation systems and the associated environmental benefits. -Note,

New Jersey's Clean Energy Program Protocols to Measure Resource Savings Formatted: Space Before: 6 pt, After: 6 pt

Formatted: Space Before: 6 pt, After: 6 pt

**Formatted:** Space Before: 6 pt, After: 6 pt

Formatted: Space Before: 6 pt, After: 6 pt

Formatted: Space Before: 6 pt, After: 6 pt

however, that renewable energy protocols are different from those required for REC certification in the state of New Jersey.

The protocols in this document focus on the determination of the per unit savings for the energy efficiency measures, and the per unit generation for the renewable energy or distributed generation measures, included in the current programs approved by the Board. The number of adopted units to which these per unit savings or avoided generation apply are captured in the program tracking and reporting process, supported by market assessments for some programs. -The unit count will reflect the direct participation and, through market assessments, the number of units due to market effects in comparison to a baseline level of adoptions. -The protocols report gross savings and generation only. -Free riders and free drivers are not addressed in these Protocols.- Further research in this area is planned.

The outputs of the Protocols are used to support:

- Regulatory Reportingreporting
- Cost-Effectiveness Analysis-effectiveness analysis
- Program <u>Evaluation</u>evaluation
- Performance <u>Incentivesincentives</u> for the <u>Market Managersmarket managers</u>

These Protocols provide the methods to measure per unit savings for program tracking and reporting. -An annual evaluation plan prepared by the <u>Center for Energy, Economic</u> and Environmental Policy (<u>CEEEP)NJCEP Evaluation Contractor</u> outlines the plans for assessing markets including program progress in transforming markets, and to update key assumptions used in the Protocols to assess program energy impacts. -Reporting provides formats and definitions to be used to document program expenditures, participation rates, and program impacts, including energy and resource savings. -The program tracking systems, that support program evaluation and reporting, will track and record the number of units adopted due to the program, and assist in documenting the resource savings using the per unit savings values in the Protocols. -Cost benefit analyses prepared by <u>CEEEP</u> and other evaluation contractors<u>NJCEP EvaluationContractors</u> assesses the impact of programs, including market effects, and their relationship to costs in a multi-year analysis.

## **Types of Protocols**

In general, energy and demand savings will be measured using measured and customer data as input values in algorithms in the protocols, tracking systems, and information from the program application forms, worksheets, and field tools.

The following table summarizes the spectrum of protocols and approaches to be used for measuring energy and resource savings. -No one protocol approach will serve all programs and measures.

<ol> <li>The application form that the customer or customer's agent submits with basic information.</li> <li>Application worksheets and field tools with more detailed site-specific data, input values, and calculations (for some programs).</li> <li>Program tracking systems that compile data and may do some calculations.</li> <li>Protocols that contain algorithms and rely on standard or site-specific input values based on measured dataParts or all of the protocols may ultimately be implemented within the tracking system, the application forms and worksheets, and the field tools.</li> </ol>		Formatted: Space Before: 3 pt, After: 3 pt	
Algorithms			
The algorithms that have been developed to calculate the energy and or demand savings are driven by a change in efficiency level for the installed measure compared to a baseline level of efficiencyThis change in efficiency is reflected in both demand and energy savings for electric measures and energy savings for gasFollowing are the basic algorithms.		Formatted: Space Before: 6 pt, After: 6 pt	
Electric Demand Savings = $\Delta kW = kW_{\text{baseline}} - kW_{\text{energy efficient measure}}$			
Electric Energy Savings = $\Delta kW X EFLH$			
Electric Peak Coincident Demand Savings = AkW X Coincidence Factor			
Gas Energy Savings = ABtuh X EFLH			
Where:			
EFLH = Equivalent Full Load Hours of operation for the installed measure. Total annual energy use (kWh) of an end use over a range of operating conditions divided by the connected full load of the end use in kW.	-		
ABtuh = Btuh <sub>baseline input</sub> Btuh <sub>energy efficient measure input</sub>			
Other resource savings will be calculated as appropriate.			
Specific algorithms for each of the program measures may incorporate additional factors to reflect specific conditions associated with a program or measureThis may include factors to account for coincidence of multiple installations, or interaction between different measures.		Formatted: Space Before: 6 pt, After: 6 pt	
1			
New Jersey's Clean Energy ProgramPage 11Protocols to Measure Resource Savings	1		

When building simulation software programs are used to develop savings estimates for several measures in a comprehensive project, as in the Pay for Performance Program, the specific algorithms used are inherent in the software and account for interaction among measures by design. -Detailed Simulation Guidelines have been developed for the Pay for Performance Program and are included in the Pay for Performance Program Guidelines. These Guidelines should be followed when building simulation is used to develop savings estimates. As stated in the Guidelines, simulation software must be compliant with ASHRAE 90.1 2004 Section 11 or Appendix G.

Formatted: Space Before: 6 pt, After: 6 pt

# **Data and Input Values**

	protocols are documented in the baseline studies or other market informationBaselines will be updated to reflect changing codes, practices and market transformation effects.	
	For the Direct Install and Low Income programs, some $\Delta$ kW, $\Delta$ kWh, and gas energy savings values are based on high efficiency equipment versus existing equipment, where the programs specifically target early retirement or upgrades that would not otherwise occurProtocols for the Direct Install Program include degradation tables to calculate the efficiency of the replaced unit.	Formatted: Space Before: 6 pt, After: 6 pt
	The Pay for Performance Program is a comprehensive program that requires participants to implement energy efficiency improvements that will achieve a minimum of 15% reduction in total source energy consumptionDue to the building simulation and measurement and verification (M&V) requirements associated with this Program, the baseline is the existing energy consumption of the facility, as reported through the U.S. EPA's Portfolio Manager benchmarking software.	Formatted: Space Before: 6 pt, After: 6 pt
	Renewable energy and distributed generation program protocols assume that any electric energy or capacity produced by a renewable energy or distributed generation system displaces electric energy and capacity from the PJM grid.	Formatted: Space Before: 6 pt, After: 6 pt
I	<b>Resource Savings in Current and Future Program Years</b>	
	The Protocols support tracking and reporting the following categories of energy and resource savings:	Formatted: Space Before: 6 pt, After: 6 pt
	<ol> <li>Savings or generation from installations that were completed in the program year and prior program years due to the program's direct participation and documented market effects.</li> </ol>	Formatted: Space Before: 3 pt, After: 3 pt
	<ol> <li>Savings or generation from program participant future adoptions due to program commitments.</li> </ol>	
	3. Savings or generation from future adoptions due to market effects.	
-	Prospective Application of the Protocols	
	The protocols will be applied prospectivelyThe input values are from the program application forms and standard input values (based on measured data including metered data and evaluation results)The protocols will be updated periodically based on evaluation results and available data, and then applied prospectively for future program years.	

### **Resource Savings**

### Electric

Protocols have been developed to determine the electric energy and coincident peak demand savings.

Annual Electric energy savings are calculated and then allocated separately by season (summer and winter) and time of day (on-peak and off-peak). -Summer coincident peak demand savings are calculated using a demand savings protocol for each measure that includes a coincidence factor. -Application of this coincidence factor converts the demand savings of the measure, which may not occur at time of system peak, to demand savings that is expected to occur during the Summer On-Peak period. -These periods for energy savings and coincident peak demand savings are defined as:

	Energy Savings	Coincident Peak	
		Demand Savings	
Summer	May through September	June through August	-
Winter	October through April	NA	•
On Peak (Monday -	8:007 a.m. to 8:0011	12 <del>:00</del> p.m. to 8 <del>:00</del> p.m.	
Friday)	p.m.		
Off Peak	M-F <u>8:0011</u> p.m. to	NA	
	<del>8:00<u>7</u></del> a.m.		
	All day weekends and holidays		

The time periods for energy savings and coincident peak demand savings were chosen to best fit the seasonal avoided cost patterns for electric energy and capacity that were used for the energy efficiency program cost effectiveness purposes. -For energy, the summer period May through September was selected based on the pattern of avoided costs for energy at the PJM level. -In order to keep the complexity of the process for calculating energy savings benefits to a reasonable level by using two time periods, the knee periods for spring and fall were split approximately evenly between the summer and winter periods.

For capacity, the summer period June through August was selected to match the highest avoided costs time period for capacity. -The experience in PJM and New Jersey has been that nearly all system peak events occur during these three months. -Coincidence factors are used to calculate energy efficiency factors on peak demand.- Renewable energy and distributed generation systems are assumed to be operating coincident with the PJM system peak. -This assumption will be assessed in the impact evaluation. Formatted: Space Before: 6 pt, After: 6 pt

### Natural Gas

Protocols have been developed to determine the natural gas energy savings on a seasonal **•** basis. -The seasonal periods are defined as:

Summer — April through September

Winter - October through March

The time periods for gas savings were chosen to best fit the seasonal avoided gas cost pattern that was used for calculating energy efficiency program benefits for cost effectiveness purposes. -However, given the changing seasonal cost patterns for gas supply, different time periods may be more appropriate to reflect a current outlook for the seasonal pattern, if any, at the time that the avoided cost benefits are calculated. -The seasonal factors used in the following protocols that correspond to the above time periods reflect either base load or heating load usage. -In the case of base load, one twelfth of the annual use is allocated to each month.- In the case of heating load, the usage is prorated to each month based on the number of normal degree-days in each month. -This approach makes it relatively easy to calculate new seasonal factors to best match different avoided cost patterns.

### **Other Resources**

Some of the energy savings measures also result in environmental benefits and the saving of other resources. -Environmental impacts are quantified based on statewide-conversion factors supplied by the NJDEP for electric, gas, and oil energy savings. Where identifiable and quantifiable these other key resource savings, such as oil, will be estimated. -Oil and propane savings are the major resources that have been identified.- If other resources are significantly impacted, they will be included in the resource savings estimates.

#### **Post-Implementation Review**

Program administrators will review application forms and tracking systems for all measures and conduct field inspections on a sample of installations. For some programs and jobs (e.g., custom, large process, large and complex comprehensive design), post-installation review and on site verification of a sample of application forms and installations will be used to ensure the reliability of site specific savings estimates.

## Adjustments to Energy and Resource Savings

#### Coincidence with Electric System Peak

Coincidence factors are used to reflect the portion of the connected load savings or generation that is coincident with the electric system peak.

Formatted: Space Before: 6 pt, After: 6 pt

Formatted: Space Before: 6 pt, After: 6 pt

Formatted: Space Before: 6 pt, After: 6 pt

Formatted: Space After: 0 pt

Formatted: Space Before: 6 pt

#### Measure Retention and Persistence of Savings

The combined effect of measure retention and persistence is the ability of installed measures to maintain the initial level of energy savings or generation over the measure life. Measure retention and persistence effects were accounted for in the metered data that were based on C&I installations over an eight year period. As a result, some protocols incorporate retention and persistence effects in the other input values. For other measures, if the measure is subject to a reduction in savings or generation over time, the reduction in retention or persistence is accounted for using factors in the calculation of resource savings (e.g., in-service rates for residential lighting measures, degradation of photovoltaic systems).

#### Interaction of Energy Savings

Interaction of energy savings is accounted for in certain programs as appropriate. -For all • other programs and measures, interaction of energy savings is zero.

For the Residential New Construction program, the interaction of energy savings is accounted for in the home energy rating tool that compares the efficient building to the baseline or reference building and calculates savings.

For the <u>Residential and</u> Commercial and Industrial Efficient Construction program, the energy savings for lighting is increased by an amount specified in the protocol to account for HVAC interaction.

For commercial and industrial custom measures, interaction where relevant is accounted for in the site-specific analysis. -In the Pay for Performance Program, interaction is addressed by the building simulation software program.

### **Calculation of the Value of Resource Savings**

The calculation of the value of the resources saved is not part of the protocols. -The protocols are limited to the determination of the per unit resource savings in physical terms.

In order to calculate the value of the energy savings for reporting and other purposes, the energy savings are determined at the customer level and then increased by the amount of the transmission and distribution losses to reflect the energy savings at the system level. The energy savings at the system level are then multiplied by the appropriate avoided costs to calculate the value of the benefits.

System Savings = (Savings at Customer)  $\frac{1}{2}$  (T&D Loss Factor)

Value of Resource Savings = (System Savings)  $\frac{x}{2}$  (System Avoided Costs + Environmental Adder) + (Value of Other Resource Savings)

New Jersey's Clean Energy Program Protocols to Measure Resource Savings Formatted: Space Before: 6 pt, After: 6 pt

The value of the benefits for a particular measure will also include the value of the water, oil, maintenance and other resource savings where appropriate. -Maintenance savings will be estimated in annual dollars levelized over the life of the measure.

# **Transmission and Distribution System Losses**

The protocols calculate the energy savings at the customer level. -These savings need to be increased by the amount of transmission and distribution system losses in order to determine the energy savings at the system level. -The following loss factors multiplied by the savings calculated from the protocols will result in savings at the supply level.

### **Electric Loss Factor**

The electric loss factor applied to savings at the customer meter is 1.076081<sup>1,2</sup> for both energy and demand. -The electric system loss factor was developed to be applicable to statewide programs. Therefore, average system losses at the margin based on a 10 year (2001 to 2010) average of the New Jersey state electricity supply and disposition dataset from the U.S. Energy Information Administration (EIA).

### **Gas Loss Factor**

The gas loss factor is 1.0. -The gas system does not have losses in the same sense that the electric system does.- All of the gas gets from the "city gate" (delivery point to the distribution system) to the point of use except for unaccounted for gas (such as theft), gas lost due to system leakage or loss of gas that is purged when necessary to make system repairs. -Since none of these types of "losses" is affected by a decrease in gas use due to energy efficiency at the customer, there are no losses for which to make any adjustment. Therefore, a system loss factor of 1.0 is appropriate for gas energy efficiency savings.

These electric and gas loss factors reflect losses at the margin and are a consensus of the electric and gas utilities.

# **Calculation of Clean Air Impacts**

The amount of air emission reductions resulting from the energy savings are calculated using the energy savings at the system level and multiplying them by factors developed by the New Jersey Department of Environmental Protection (NJDEP).Pennsylvania-New Jersey-Maryland Interconnection (PJM) for electric emissions and US EPA for natural gas emissions.

All factors are provided by the NJ Department of Environmental Protection and are on an average system basis. They will be updated as new factors become available.

### **Measure Lives**

Measure lives are provided in Appendix A for informational purposes and for use in other applications such as reporting lifetime savings or in benefit cost studies that span more than one year. -The Pay for Performance Program uses the measure lives as included in Appendix A to determine measure-level and project-level cost effectiveness.

# **Protocols for Program Measures**

I

The following pages present measure or project-specific protocols.- In those instances where measures are applicable to more than one program, the measures apply to all such programs unless otherwise specified.

Formatted: Space Before: 6 pt, After: 6 pt

### Formatted: Keep with next **Residential Electric HVAC** Formatted **Protocols** Formatted: Space Before: 6 pt, After: 6 pt The measurement plan for residential high efficiency cooling and heating equipment is based on algorithms that determine a central air conditioners or heat pump's cooling/heating energy use and peak demand. -Input data is based both on fixed assumptions and data supplied from the high efficiency equipment rebate application form. -The algorithms also include the calculation of additional energy and demand savings due to the required proper sizing of high efficiency units. Formatted: Space Before: 6 pt, After: 6 pt The savings will be allocated to summer/winter and on-peak/off-peak time periods based on load shapes from measured data and industry sources. -The allocation factors are documented below in the input value table. Formatted: Space Before: 6 pt, After: 6 pt The protocols applicable for this program measure the energy savings directly related to the more efficient hardware installation. -Estimates of energy savings due to the proper sizing of the equipment are also included. Formatted: Space Before: 6 pt, After: 6 pt The following is an explanation of the algorithms used and the nature and source of all required input data. Central Air Conditioner (A/C) & Air Source Heat Pump (ASHP) & Mini-split (AC or HP) Algorithms Formatted: English (U.S.) Central Air Conditioner (A/C) & Air Source Heat Pump (ASHP) Cooling Energy Consumption and Peak Demand Savings - Central A/C & ASHP (High Formatted: Font: Not Italic Efficiency Equipment Only): Formatted: Indent: Left: 0" Formatted: Font: Not Italic Energy ImpactSavings (kWh) = CAPY/1000 X/yr) = Tons \* 12 kBtuh/Ton \* Formatted: None, Indent: Left: 0" $(1/\text{SEER}_b - 1/\text{SEER}_q) \times \text{EFLH}_c$ Formatted: None, Indent: Left: 0", First line: 0' Peak Demand ImpactSavings (kW) = CAPY/1000 X Tons \* 12 kBtuh/Ton \* (1/EERb Formatted: None, Indent: Left: 0" $-1/\text{EER}_q$ ) $\times \text{CF}$ Formatted: Indent: Left: 0" Heating Energy Savings –(ASHP and Mini-Split): Formatted: Font: Not Italic Formatted: Normal, Indent: First line: 0" Energy ImpactSavings (kWh) = CAPY/1000 X/yr) = Tons \* 12 kBtuh/Ton \* Formatted: Font: Not Italic $(1/\text{HSPF}_b - 1/\text{HSPF}_q) \times \text{EFLH}_h$ Formatted: Indent: Left: 0" **Cooling** Proper Sizing and Quality Installation Verification (QIV):

- 26.<u>18.</u> 30% savings (from Zaloum, C. Lafrance, M. Gusdorf, J. "Drain Water Heat Recovery Characterization and Modeling" Natural Resources Canada. 2007. Savings vary due to a number of factors including make, model, installation-type, and household behaviors.) multiplied by standard electric resistance water heating baseline annual usage of 4,857 kWh cited in source #23 above.
- 27:19. Demand savings are estimated based on electric DHW demand of 2.13kW and 20% CF as in cited source #21 adjusting for the proportional difference of 30% savings relative to the 70% solar fraction: 0.426\*0.3/0.9 = 0.142.
  - 28. AHRI directory. Baseline values are the least efficient "Geothermal Water to Air Heat Pumps" active in the directory, downloaded May 18, 2015.

#### Combined space and water heating (Combo)

Participants installing a qualifying boiler or furnace and a qualifying water heater at the same time earn a special incentive. For savings calculations, there is no special consideration. The heating system savings are calculated according to the appropriate algorithm and the water heating savings are calculated separately according to the system type.

# **Residential Gas HVAC**

### **Protocols**

The following two algorithmssections detail savings <u>calculations</u> for gas <u>space</u> heating and <u>gas</u> water heating equipment<u>in residential applications</u>. They are to be used to determine gas energy savings between baseline standard units and the high efficiency units promoted in the program. The input values are based on data on typical customers supplied by the gas utilities, an analysis by the Federal Energy Management Program (FEMP), and customer information on the application form, confirmed with manufacturer data. The energy values are in therms.

## <u>Furnaces</u>

This section provides energy savings algorithms for qualifying gas and oil furnaces installed in residential settings. The input values are based on the specifications of the actual equipment being installed, federal equipment efficiency standards, and the most recent impact evaluation of the residential Warm and Cool Advantage programs (2009).

This measure applies to replacement of failed equipment or end of useful life. The baseline unit is a code compliant unit with an efficiency as required by IECC 2015, which is the current residential code adopted by the state of New Jersey.

Gas Savings (Drain Water Heat Recover) = GsavDWHR \* Baseline Water Heater Usage

#### **Definition of Variables**

 $EF_{q}$  = Energy factor of the qualifying energy efficient water heater.

-Note: For qualifying units not rated with an Energy Factor, the estimated EF<sub>4</sub> shall be used:

 $-Est. EF_q = Q_{out}/Q_{in}$ 

 $=41,094^{6}/(41,094/TE + Volume*SLratio*24hours)$ 

TE = Thermal (or Recovery) Efficiency of the unit as a percentage Where: Volume = Volume of storage water heater, in gallons. SLratio = Average ratio of rated standby losses water heater (BTU loss per hour for > 90% TE units less than 130 Gallons =  $9.73^{7}$ 

Gas & Propane Tankless Water Heaters<sup>1</sup>:  $EF_{k} = 00.82 - (0.0019 * Gallons of Capacity)$ Gas & Propane Storage or Power Vented Water Heaters<sup>+</sup>:

55 gallons or less: EF<sub>b</sub> = 0.675 (0.0015 \* Gallons of Capacity)

56 gallons or more:  $EF_{b} = 0.8012$  (0.00078 \* Gallons of Capacity)

Summary of Inputs

#### **Furnace Assumptions**

Baseline Water Heater Usage = Annual usage of the baseline water heater, in therms.

GsavSHW = Gas savings, in therms, for a solar hot water installation augmented by a new gas hot water heater.

GsavDWHR = Gas savings, as a percentage, for a drain water heat recovery installation in a home with a gas hot water heater.

## <u>Boilers</u>

This section provides energy savings algorithms for qualifying boilers installed in residential settings. The input values are based on the specifications of the actual equipment being installed, federal equipment efficiency standards, and the most recent impact evaluation of the residential Warm and Cool Advantage programs (2009).

This measure applies to replacement of failed equipment or end of useful life. The baseline unit is a code compliant unit with an efficiency as required by IECC 2015, which is the current residential code adopted by the state of New Jersey.

Algorithms

<u>Fuel Savings (MMBtu/yr) =  $Cap_{in} * EFLH_{h} * ((AFUE_{g}/AFUE_{b})-1) / 1000 kBtu/MMBtu</u></u>$ 

# Definition of Variables

<u>Cap<sub>in</sub> = Input capacity of qualifying unit in kBtu/hour</u>

 $EFLH_{b}$  = The Equivalent Full Load Hours of operation for the average unit during the heating season in hours

 $\underline{AFUE}_q = Annual Fuel Utilization Efficiency of the qualifying boiler}$ 

 $\underline{AFUE}_{b} = Annual Fuel Utilization Efficiency of the baseline boiler$ 

Summary of Inputs

# **Combination Boilers**

This section provides energy savings algorithms for qualifying gas combination boilers installed in residential settings. A combination boiler is defined as a boiler that provides domestic hot water and space heating. The input values are based on the specifications of the actual equipment being installed, federal equipment efficiency standards, DOE2.2 simulations completed by the New York State Joint Utilities and regional estimates of average baseline water heating energy usage.

This measure assumes the existing boiler system has failed or is at end of useful life and is replaced with a combination boiler. The baseline boiler unit has an efficiency as required by IECC 2015, which is the current residential code adopted by the state of New Jersey. For the water heating component, this measure assumes that the baseline water heater is a storage water heater, and customers replacing existing tankless water heaters are not eligible.

Note, that as of June 12, 2017, the Federal Trade Commission has published a final rule updating the EnergyGuide label to reflect recent changes by the Department of Energy to the Code of Federal Regulations regarding the use of uniform energy factor (UEF) rather than the traditional energy factor (EF)<sup>8</sup> for consumer and commercial water heaters. The UEF is newest measure of water heater overall efficiency. The higher the UEF value is, the more efficient the water heater. UEF is determined by the Department of Energy's test method outlined in 10 CFR Part 430, Subpart B, Appendix E.<sup>9</sup>

# Instantaneous Water Heaters

This section provides energy savings algorithms for qualifying instantaneous hot water heaters installed in residential settings. This measure assumes that the baseline water heater is either a code stand alone storage water heater, or an code instantaneous water heater. The input values are based on federal equipment efficiency standards and regional estimates of average baseline water heating energy usage.

Note, that as of June 12, 2017, the Federal Trade Commission has published a final rule updating the EnergyGuide label to reflect recent changes by the Department of Energy to the Code of Federal Regulations regarding the use of uniform energy factor (UEF) rather than the traditional energy factor (EF)<sup>15</sup> for consumer and commercial water heaters. The UEF is newest measure of water heater overall efficiency. The higher the UEF value is, the more efficient the water heater. UEF is determined by the Department of Energy's test method outlined in 10 CFR Part 430, Subpart B, Appendix E.<sup>16</sup>

## Algorithms

Fuel Savings (MMBtu/yr) =  $(1 - (UEF_b / UEF_q)) \times Baseline Water Heater Usage$ 

## Definition of Variables

 $UEF_q = Uniform$  energy factor of the qualifying energy efficient water heater.  $UEF_b = Uniform$  energy factor of the baseline water heater. In New Jersey the 2015 International Energy Conservation Code (IECC) generally defines the residential energy efficiency code requirements, but the IECC does not include residential service water heating provisions, leaving federal equipment efficiency standards to define baseline.

Baseline Water Heater Usage = Annual usage of the baseline water heater

## Summary of Inputs

instantaneous water Heaters					
<b>Component</b>	<u>Type</u>	Value	<b>Source</b>		
$\underline{\mathrm{UEF}}_q$	<u>Variable</u>		Application

The referenced federal standards for the baseline UEF are dependent on both draw pattern and tank size. A weighted average baseline UEF was calculated with a medium draw pattern from the referenced federal standards and water heating equipment market data from the Energy Information Association 2009 residential energy consumption survey for NJ<sup>17</sup> assuming tank sizes of 30 gallons for small units, 40 gallons for medium units, and 55 gallons for large units.

# **Residential Low Income Program**

# **Protocols**

The Protocols set out below are applicable to both the Comfort Partners component of the **Formatted**: Space Before: 6 pt, After: 6 pt Low-income Program currently implemented by the State's electric and gas utilities and the Weatherization Assistance component of the Low-income Program implemented by the New Jersey Department of Community Affairs (DCA).

The savings protocols for the low-income program are based upon estimated per unit installed savings. -In some cases, such as lighting and refrigerators, the savings per unit estimate is based on direct observation or monitoring of the existing equipment being replaced. -For other measures, for example air sealing and insulation, the protocols calculation is based on an average % savings of pre-treatment consumption.

## **Base Load Measures**

# Efficient Lighting

Savings from installation of screw-in CFLs, high performance fixtures, fluorescent torchieres, LEDs and LED nightlights are based on a straightforward algorithm that calculates the difference between existing and new wattage, and the average daily hours of usage for the lighting unit being replaced.

## Algorithm

Compact Fluorescent Screw In Lamp <u>Electricity ImpactEnergy Savings</u> (kWh/yr) = ((CFL<sub>watts</sub>) <u>X</u>\* (CFL<sub>hours</sub> <u>X</u>\* 365))/1000

Peak Demand  $\frac{\text{Impact}Savings}{\text{Margon}}$  (kW) = (CFL<sub>watts</sub>)  $\frac{\text{X}^{*}}{\text{X}}$  Light CF

## Efficient Fixtures

<u>Electricity ImpactEnergy Savings</u> (kWh/yr) = ((Fixt<sub>watts</sub>) X\* (Fixt<sub>hours</sub> X\* 365))/1000

Peak Demand  $\frac{\text{Impact}Savings}{\text{Savings}}$  (kW) = (Fixt<sub>watts</sub>)  $X^*$  Light CF

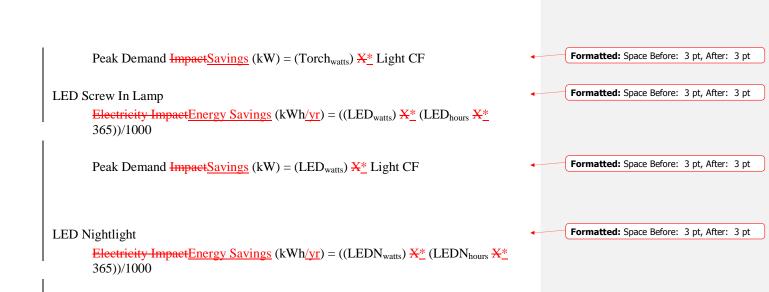

## **Efficient Torchieres**

Electricity ImpactEnergy Savings (kWh/yr) = ((Torch<sub>watts</sub>) X<sup>\*</sup> (Torch<sub>hours</sub> X<sup>\*</sup> 365))/1000

## Indirect Hot Water Heaters

Wisconsin's 2013 Focus on Energy Deemed Savings are as follows.<sup>19</sup>

$$\Delta Therm = Therm_{Std} - Therm_{Eff}$$

 $Therm_{Out} = EF_{Std} \times Therm_{StdTank}$ 

 $Therm_{Std} = Standby_{Std} \times 8,760 \times 1/100,000/AFUE_{Std} + Therm_{Out} \times 1/AFUE_{std}$ +-Average hot water use per person were taken from: Lutz, James D., Liu, Xiaomin, McMahan, James E., Dunham, Camilla, Shown, Leslie J., McCure, Quandra T; "Modeling patterns of hot water use in households;" LBL-37805 Rev. Lawrence Berkeley Laboratory, 1996.

 $Therm_{Eff} = Standby_{Eff} \times 8,760 \times 1/100,000/AFUE_{Eff} + Therm_{out} \times 1/AFUE_{Eff}$ 

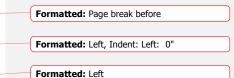

$$Standby_{Std} = Vol_{Std} \times \left(\frac{{}^{\circ}F}{hr_{Std}}\right) \times 8.33$$

$$Standby_{Eff} = Vol_{Eff} \times \left(\frac{{}^{\circ}F}{hr_{Eff}}\right) \times 8.33$$

#### Water heater pipe wrap

This section provides energy savings algorithms for insulation on domestic hot water heater pipes. Un-insulated hot water carrying pipes lose considerable heat to outside air due to high thermal conductivity. In order to reduce this heat loss, pipes can be covered with a layer of insulation, which will reduce source heating demand, resulting in significant energy savings. The baseline case assumes un-insulated copper pipes and the qualifying condition assumes polyolefin (Polyethylene) Foam Tube insulation at 3/8" thick for 1/2" pipe and 1/2" thick for 3/4" pipe.

#### Algorithms

Energy Savings (kWh/yr) =  $AKW_W \times L$ 

<u>Fuel Savings (Ccf/yr) = ACCF<sub>W</sub> × L</u>

#### Definition of Variables

 $AKW_W = Annual electric savings per linear foot of heating pipe insulation ACCF_W = Annual gas savings per linear foot of heating pipe insulation$ 

L = Length of heating pipe insulation in ft

#### Summary of Inputs

<u>Water Heater Pipe Wrap</u>					
<b>Component</b>	<b>Type</b>	Value	Source		
<u>AKWw</u>	<u>Variable</u>	See Table Below	<u>1</u>

#### Sources

1. NAIMA, 3E Plus software tool, Version 4.0, Released 2005; available from: https://insulationinstitute.org/tools-resources/free-3e-plus/

#### Efficient Refrigerators

The eligibility for refrigerator replacement is determined by comparing monitored consumption for the existing refrigerator with the rated consumption of the eligible replacement. -Estimated savings are directly calculated based on the difference between these two values.- Note that in the case where an under-utilized or unneeded refrigerator unit is removed, and no replacement is installed, the Ref<sub>new</sub> term of the equation will be zero.

#### Algorithm

<u>Electricity ImpactEnergy Savings</u> (kWh/yr) = Ref<sub>old</sub> - Ref<sub>new</sub>

Peak Demand  $\frac{\text{Impact}Savings}{\text{Impact}Savings}$  (kW) = (Ref<sub>old</sub> - Ref<sub>new</sub>) \*(Ref DF)

#### **Space Conditioning Measures**

When available, gas heat measure savings will be based on heating use. -If only total gas use is known, heating use will be estimated as total use less 300 therms.

#### Air Sealing

It is assumed that air sealing is the first priority among candidate space conditioning measures. -Expected percentage savings is based on previous experiences with measured savings from similar programs. -Note there are no summer coincident electric peak demand savings estimated at this time.

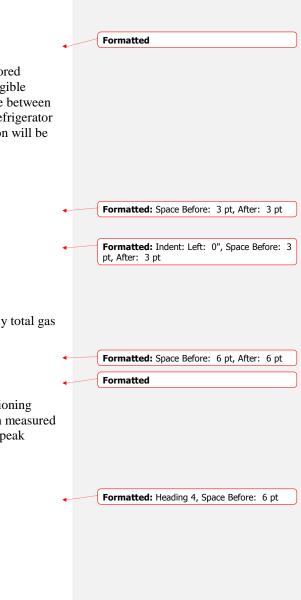

#### Algorithm

## <u>Algorithm</u>

Electricity ImpactEnergy Savings (kWh/yr) = ESC<sub>pre</sub> X\* 0.05

# Algorithms

Fuel Savings (MMBtu/yr) =  $Cap_{in} \times EFLH_h \times (1/SSE_b - 1/SSE_g) / 1,000kBtu/MMBtu$ 

#### Definition of Variables

<u>Cap<sub>in</sub> = input capacity of existing unit in kBtu/hr</u>

 $EFLH_h = equivalent full load heating hours$ 

<u>SSE<sub>b</sub> = Steady state efficiency of baseline gas HVAC equipment</u>

SSE<sub>q</sub> = Steady state efficiency of repaired gas HVAC equipment

## Summary of Inputs

# **Gas HVAC Repairs**

<b>Component</b>	<u>Type</u>	Value	Source	
Furnace rating	<u>Variable</u>		Application	
<u>EFLH<sub>h</sub></u>	Fixed	<u>965</u>	<u>NJ utility analysis of heating customers,</u> <u>annual gas heating usage</u>	
<u>SSEq</u>	<u>Variable</u>		Application	
<u>SSE</u> b	<u>Variable</u>		Application	

Example: If a furnace has a 90 kBtu/hr input capacity, baseline efficiency of 85%, and post repairs efficiency of 90%, the fuel savings would be calculated as FS = 90kBtu/hr × 965 hr × (1/0.85 – 1/0.90)/1,000kBtu/MMBtu = 5.67 MMBtu/yr.

	Other "Custom" Measures	-	Formatted: Page break before
	In addition to the typical measures for which savings algorithms have been developed, it is assumed that there will be niche opportunities that should be identified and addressed. The savings for these custom measures will be reported based on the individual calculations supplied with the reportingAs necessary the program working group will develop specific guidelines for frequent custom measures for use in reporting and contractor tracking.		
I	Definition of Terms		
	$CFL_{watts}$ = Average watts replaced for a CFL installation.		Formatted: Space Before: 3 pt, After: 3 pt
	CFL <sub>hours</sub> = Average daily burn time for CFL replacements.		Formatted: Space Before: 3 pt, After: 3 pt
	Fixt <sub>watts</sub> = Average watts replaced for an efficient fixture installation.		Formatted: Space Before: 3 pt, After: 3 pt
	Fixt <sub>hours</sub> = Average daily burn time for CFL replacements.		Formatted: Space Before: 3 pt, After: 3 pt
	Torch <sub>watts</sub> = Average watts replaced for a Torchiere replacement.		Formatted: Space Before: 3 pt, After: 3 pt
	Torch <sub>hours</sub> = Average daily burn time for a Torchiere replacements.		Formatted: Space Before: 3 pt, After: 3 pt
	LED <sub>watts</sub> = Average watts replaced for an LED installation.		Formatted: Space Before: 3 pt, After: 3 pt
	LED <sub>hours</sub> = Average daily burn time for LED replacements.		Formatted: Space Before: 3 pt, After: 3 pt
	LEDN <sub>watts</sub> = Average watts replaced for an LED nightlight installation.		Formatted: Space Before: 3 pt, After: 3 pt
	LEDN <sub>hours</sub> = Average daily burn time for LED nightlight replacements.		Formatted: Space Before: 3 pt, After: 3 pt
	Light $CF =$ Summer demand coincidence factor for all lighting measures. Currently fixed at 5%.		Formatted: Space Before: 3 pt, After: 3 pt
	$HW_{eavg} = Average$ electricity savings from typical electric hot water measure package.		Formatted: Space Before: 3 pt, After: 3 pt
	$HW_{gavg} = Average$ natural gas savings from typical electric hot water measure package.		Formatted: Space Before: 3 pt, After: 3 pt
	HW <sub>watts</sub> = Connected load reduction for typical hot water efficiency measures		Formatted: Space Before: 3 pt, After: 3 pt

HW CF = Summer demand coincidence factor for electric hot water measure package. Currently fixed at 75%.		Formatted: Space Before: 3 pt, After: 3 pt
$Ref_{old} = Annual energy consumption of existing refrigerator based on on-site monitoring.$	•	Formatted: Space Before: 3 pt, After: 3 pt
$Ref_{new} = Rated$ annual energy consumption of the new refrigerator.	•	Formatted: Space Before: 3 pt, After: 3 pt
Ref DF = kW /kWh of savingsRefrigerator demand savings factor.		Formatted: Space Before: 3 pt, After: 3 pt
Ref CF = Summer demand coincidence factor for refrigeration. Currently 100%, diversity accounted for in the Ref DF factor.		Formatted: Space Before: 3 pt, After: 3 pt
$ESC_{pre} = Pre-treatment$ electric space conditioning consumption.		Formatted: Space Before: 3 pt, After: 3 pt
ECool <sub>pre</sub> = Pre-treatment electric cooling consumption.		Formatted: Space Before: 3 pt, After: 3 pt
EFLH = Equivalent full load hours of operation for the average unitThis value is currently fixed at 650 hours.		Formatted: Space Before: 3 pt, After: 3 pt
AC CF = Summer demand coincidence factor for air conditioning. Currently 85%.		Formatted: Space Before: 3 pt, After: 3 pt
Capy = Capacity of Heat Pump in Btuh		Formatted: Space Before: 3 pt, After: 3 pt
EER = Energy Efficiency Ratio of average heat pump receiving charge and air flow serviceFixed at 9.2		Formatted: Space Before: 3 pt, After: 3 pt
HP CF = Summer demand coincidence factor for heat pump. Currently fixed at 70%.	•	Formatted: Space Before: 3 pt, After: 3 pt
DSF = Demand savings factor for charge and air flow correctionCurrently fixed at 7%.		Formatted: Space Before: 3 pt, After: 3 pt
$GC_{pre} = Pre-treatment$ gas consumption.		Formatted: Space Before: 3 pt, After: 3 pt
GH <sub>pre</sub> = Pre-treatment gas space heat consumption (=.GC <sub>pre</sub> less 300 therms if only total gas use is known.	•	Formatted: Space Before: 3 pt, After: 3 pt
WS = Water Savings associated with water conservation measures. Currently fixed at 3,640 gallons per year per home receiving low-flow showerheads, plus 730 gallons saved per year aerator installed.		Formatted: Space Before: 3 pt, After: 3 pt

# **Residential New Construction Program**

# **Protocols**

- Single-Family, Multi-Single and Low-Rise Multifamily Building Shell

Energy-Whole building energy savings due to thermal shell and mechanical equipment improvements in residential new construction and "gut" renovation projects are calculated using outputs from REM/Rate<sup>TM</sup>RESNET accredited Home Energy Rating System (HERS) modeling software<sup>20</sup>. -All program homes are modeled in REM/Rateusing accredited software to estimate annual energy consumption for heating, cooling-and, hot water..., and other end uses within the HERS asset rating. Standards for energy efficient new construction in New Jersey are based on national platforms including IECC 2015, EPA ENERGY STAR® Certified New Homes Program, EPA ENERGY STAR Multifamily High-Rise Program (MFHR), and the DOE Zero Energy Ready Home (ZERH) Program. All of these pathways are based on and incorporate by reference the applicable HERS standards, including but not limited to, the Mortgage Industry National Home Energy Rating System Standard & Addenda and ANSI/RESNET/ICC Standard 30.<sup>21</sup>

# Single-Family, Multi-Single (townhomes), Low-Rise Multifamily

The program home is then modeled to a baseline specification using <u>REM/Rate'sa</u> program-specific reference home (referred to in some software as a User Defined Reference Home (or UDRH) feature. -The <u>UDRHprogram reference home specifications</u> are set according to the lowest efficiency specified by applicable codes and standards, thereby representing a New Jersey specific baseline specification is forhome against which the improved efficiency of program homes permitted prioris measured.

The NJCEP reference home shall be updated as necessary over time to and reflect the efficiency values of HERS Minimum Rated Features based on:

- The prescriptive minimum values of the IECC 2015 version applicable to the home for which savings are being calculated;
- The Federal Minimum Efficiency Standards applicable to each rated feature at the time of permitting (e.g. minimum AFUE and SEER ratings for heating and air conditioning equipment, etc.);
- An assessment of baseline practice, as available, in the event that either of the above standards reference a non-specific value (e.g. "visual inspection");
- Exclusion of specific rated features from the savings calculation in order to remove penalties for building science based best practice requirements of the

<sup>&</sup>lt;sup>20</sup> Accredited Home Energy Rating Systems (HERS) software,

http://www.remrate.com/resnet.us/professional/programs/software

<sup>&</sup>lt;sup>21</sup> http://www.resnet.us/professional/standards

program (e.g. by setting the reference and rated home to the same value for program-required mechanical ventilation);

• Other approved adjustments as may be deemed necessary.

The RNC program currently specifies three standards for program qualification:

- IECC 2015 Energy Rating Index (for homes permitted on or after March 21, 2016-)
- ENERGY STAR Certified Homes v3.1
- Zero Energy Ready Home &Zero Energy Home + RE

The difference in modeled annual energy consumption between the program and UDRHapplicable baseline reference home is the projectprojected savings for heating, hot water, cooling, lighting and appliance end uses. , appliances, and other end uses in the HERS Minimum Rated Features, as well as on-site renewable gereration, when applicable. Coincident peak demand savings are also derived from REM/Raterated modeled outputs.

The algorithms that calculate energy and demand savings are as follows:

Energy Savings = (Baseline home energy consumption – Program home energy consumption)

The following table describes the baseline characteristics of Climate Zone 4 and 5 reference homes for single-family, multi-single and low-rise multifamily buildings.

### **Residential ENERGY STAR Lighting**

Savings from <u>the</u> installation of screw-in ENERGY STAR CFLs, ENERGY STAR <u>LED</u> <u>lamps, ENERGY STAR</u> fluorescent torchieres, ENERGY STAR <u>indoor specialty LED</u> fixtures <u>and</u>, ENERGY STAR <u>outdoor</u> fixtures are based on a straightforward algorithm that calculates the difference between <u>existing the baseline lamp/fixture wattage</u> and new <u>lamp/fixture</u> wattage, and the average daily hours of usage for the lighting unit being replaced. <u>An "</u>

<u>Using the tables provided in service'' rate\_this section, the baseline lamp wattage reflects</u> the input wattage associated with a lamp that is used\_compliant with the corresponding standards included in the Energy and Independence and Security Act of 2007.

The coincidence factor (CF) discounts the peak demand savings to reflect the fact that not all lighting products purchased are actually installed kW reduction realized during the summer on-peak demand period. This is based on typical operating schedules for the geographical area covered by the program.

HVAC interactive factors are applied to capture the additional savings or penalty associated with the impact of lighting measures on the building's HVAC system. A reduction in lighting load will result in additional cooling savings during the summer period, and a gas heating penalty during the winter period.

Algorithms

Energy Savings  $\left(\frac{kWh}{yr}\right) = \frac{(Watts * Qty)_b - (Watts * Qty)_q}{1,000 \frac{Watts}{kW}} * (Hrs) * (1 + HVAC_e)$ 

Peak Demand Savings 
$$(kW) = \frac{(Watts * Qty)_b - (Watts * Qty)_q}{1,000 \frac{Watts}{kW}} * (CF) * (1 + HVAC_d)$$

Fuel Savings 
$$\left(\frac{\text{MMBtu}}{\text{yr}}\right) = \frac{(\text{Watts * Qty})_b - (\text{Watts * Qty})_q}{1,000 \frac{Watts}{kW}} * (\text{Hrs}) * (\text{HF}) * \left(\frac{0.003412}{nHeat}\right)$$

The general formDefinition of the equation for the ENERGY STARVariables	Formatted: Underline, (none)
<u>Watts<sub>b</sub> = Wattage of baseline connected fixture</u> or other high efficiency lamp	
<u>Watts<sub>q</sub> = Wattage of qualifying connected fixture or lamp</u>	
<u>Qty<sub>b</sub> = Quantity of baseline fixtures or lamps</u>	
<u>Qty<sub>q</sub> = Quantity of energy-efficient fixtures or lamps</u>	
<u>Hrs = Annual lighting operating hours</u>	

New Jersey's Clean Energy Program Protocols to Measure Resource Savings **Formatted:** Space After: 10 pt, Line spacing: Multiple 1.15 li, Allow hanging punctuation, Adjust space between Latin and Asian text, Adjust space between Asian text and numbers, Font Alignment: Auto

Formatted: English (U.S.)

CF = Coincidence factor

HVACeheat = HVAC interaction factor for annual cooling energy savings algorithm is:

HVACecool = HVAC interaction factor for annual electric heating energy savings

 $HVAC_d$  = HVAC interaction factor for peak demand reduction = 1 - ((HF / *nHeat*) \* %ElecHeat))

HF = Heating factor, or percentage of lighting savings that must be heated

*nHeat* = Efficiency of heating system

Summary of Inputs

#### **Residential ENERGY STAR Lighting**

Number of Units X Savings per Unit

Per unit savings estimates are derived primarily from a 2004 Nexus Market Research report evaluating similar retail lighting programs in New England (MA, RI and VT). Per unit savings will decrease for CFLs in operation after 2012 due to the effects of federal minimum efficiency standards for incandescent lighting. Because CFLs typically have rated lifespans of 6-8000 hours (5-7 years) and incandescent light bulbs are rated at 1000 hours (1 year), after 2013 there will be less of a difference between CFLs in service and the incandescents that they would have been replacing.

National lighting efficiency standards are being increased according to the Energy Independence and Security Act of 2007 (EISA).<sup>23</sup> EISA pertains to the efficiency of newly manufactured bulbs, not existing stock. Existing Protocol baselines and measure lifetimes will remain until the impact of the standard can be fully measured and quantified. The future EISA wattage standards are:

Energy Savings (kWh) = (CFL<sub>watts</sub>[CFL<sub>base</sub> – CFL<sub>ee</sub>]/1000) X CFL<sub>hours</sub> X 365 X CFL<sub>ISR</sub>

Demand Savings (kW) = ([CFL<sub>base</sub> - CFL<sub>ee</sub>]CFL<sub>watts</sub>/1000) X CF X CFL<sub>ISR</sub>

ENERGY STAR LED Recessed Downlights & Integral Lamps/Fixtures

Some LED products do not allow for a fixture-to-fixture comparison due to unique form factors, such as LED rope lights, sign lighting, and cove lighting.

In these instances, a similar savings and demand algorithm may be used, however with a different metric other than fixture quantity entered. For example, a comparison of watts per linear foot between LED and incandescent technologies would result in accurate energy savings calculations.

Algorithms

Peak Demand Savings (kW) =  $(\Delta kW) * (CF) * (1 + HVAC_d)$ 

Energy Savings  $\left(\frac{kWh}{yr}\right) = (\Delta kW) * (Hrs) * (1 + HVAC_e)$ 

Fuel Savings 
$$\left(\frac{\text{MMBtu}}{\text{yr}}\right) = \frac{(\text{Watts } * \text{ Qty})_b - (\text{Watts } * \text{ Qty})_q}{1,000 \frac{Watts}{kW}} * (\text{Hrs}) * (\text{HF}) * \left(\frac{0.003412}{n\text{Heat}}\right)$$

- 1. Nexus Market Research, "Impact Evaluation of the Massachusetts, Rhode Island and Vermont 2003 Residential Lighting Programs", Final Report, October 1, 2004, p. 43 (Table 4 9) The delta watts are reduced by 22.2% in the same proportion to individual CFLs (48.5W to 32.9W) following full enactment of EISA requirements.
- 2. US Department of Energy, Energy Star Calculator.
- 3. Nexus Market Research, "Impact Evaluation of the Massachusetts, Rhode Island and Vermont 2003 Residential Lighting Programs", Final Report, October 1, 2004. p. 42 (Table 4-7). These values reflect both actual installations and the % of units planned to be installed within a year from the logged sample. The logged % is used because the adjusted values (i.e. to account for differences between logging and telephone survey samples) were not available for both installs and planned installs. However, this seems appropriate because the % actual installed in the logged sample from this table is essentially identical to the % after adjusting for differences between the logged group and the telephone sample (p. 100, Table 9-3).
- RLW Analytics, "Development of Common Demand Impacts for Energy Efficiency Measures/Programs for the ISO Forward Capacity Market (FCM)", prepared for the New England State Program Working Group (SPWG), March 25, 2007, p.-IV.
- 5. The average wattage (18.4W) of the standard CFL established in the 2009 "NJCEP Residential CFL Impact Evaluation and Protocol Review", September 28, 2008, p.3–8 (Table 3–6) is adjusted by a post EISA multiplier (1.79) of the 2014 Mid-Atlantic Technical Reference Manual V4.0 for calculating the new delta watts after the incandescent bulb wattage is reduced (from 100W to 72W in 2012, 75W to 53W in 2013 and 60W to 43W and 40W to 29W in 2014).
- RLW Analytics, New England Residential Lighting Markdown Impact Evaluation, January 20, 2009.

For determining demand savings the baseline was adopted from 2009 KEMA evaluation and represents the replacement of a 65W BR30 downlight and high efficiency is the average of ENERGY STAR qualified downlights (11/10/2009) with lighting output exceeding 475 lumens. Due to the high incremental cost and limited market availability of products, the higher ISR reflects the assumption that every LED downlight purchased is directed towards immediate use.
 Mid Atlantic TRM V5

### Home Energy Reporting System

#### -Protocols

The purpose of the program is to provide information and tools that residential customers can use to make decisions about what actions to take to improve energy efficiency in their homes. The information is mailed in reports separately from a utility's regular bill to create a neighbor to neighbor comparison where homes of similar size are compared to each other, as well as targeting energy saving tips to individuals. The quantity and timing of mailed reports will vary by utility and fuel type.

#### Home Energy Reporting System

Gas Savings (Therms) = GSav<sub>HERS</sub>

### **Refrigerator/Freezer Retirement Program**

#### -Protocols

retirement program. The general form of the equation for the Refrigerator/Freezer **Formatted:** Space Before: 6 pt, After: 6 pt Retirement Program savings algorithm is:

Number of Units X<sup>\*</sup>/<sub>2</sub> Savings per Unit

To determine resource savings, the per unit estimates in the protocols will be multiplied by the number of appliance units.

New Jersey's Clean Energy Program Protocols to Measure Resource Savings Formatted: Underline

Formatted: Space Before: 6 pt, After: 6 pt

Formatted: Pattern: Clear (Light Yellow) Formatted: Body Text, Justified, Right: 0.09", Line spacing: At least 12 pt

### Algorithm

To determine resource savings, the per unit estimates in the protocols will be multiplied by the number of appliance units.

Unit savings are the product of average fridge/freezer consumption (gross annual savings), and a net to gross ratio that adjusts for both free ridership and the portion of retired units that are replaced with more efficient new units.

# **Commercial and Industrial Energy Efficient Construction**

### **C&I Electric** Protocols

#### **Baselines and Code Changes**

In general, efficiency baselines are designed to reflect current market practices - typically, the higher of applicable codes or the minimum efficiency of available new equipment - and are updated periodically to reflect upgrades in code or information from evaluation results. There are exceptions to this approach, as in the Direct Install program (see below).

Baseline data reflect ASHRAE 90.1-2007 for existing building retrofit and ASHRAE 90.1-2013 for new construction, replacement of failed equipment, end of useful life, and entire facility rehabilitation-unless otherwise noted for applications designated "2011".

#### **Building Shell**

Building shell measures identified in an approved Local Government Energy Audit (or equivalent) are eligible for incentives through the Custom and Pay for Performance program. -Savings for these measures will vary from project to project based on factors such as building size, existing levels of insulation and infiltration levels. As a result, energy savings for these installed building shell measures will be taken from what is provided in the approved <u>AuditenergyAudit and/or energy</u> analysis provided with the application submission.

### **C&I Electric Protocols**

The following measures are outlined in this section: Performance Lighting, Prescriptive Lighting, Refrigerated Case LED Lights, Lighting Controls, ECMs for Refrigeration, Electric HVAC Systems, Fuel Use Economizers, Dual Enthalpy Economizers, Occupancy Controlled Thermostats, Electric Chillers, VFDs, and Commercial Refrigeration.

#### **Performance Lighting**

For new construction and entire facility rehabilitation projects, savings are calculated by comparing the lighting power density of fixtures being installed to the baseline <del>power</del> <del>densities fromlighting power density, or "lighting power allowance," from the building code. For the state of New Jersey, the applicable building code is ASHRAE 90.1 2013.</del>

**Formatted:** Normal, Space Before: 6 pt, After: 6 pt

Lighting equipment includes fluorescent fixtures, ballasts, compact fluorescent fixtures, LED fixtures, and <u>lamps</u>, and <u>high-intensity</u> discharge fixtures such as metal halide lamps. The measurement of energy savings is based on algorithms with measurement of key variables (i.e., Coincidence Factor and Operating Hours) through end-use metering data accumulated from a large sample of participating facilities from 1995 through 1999.and high pressure sodium luminaires.

<u>Algorithms</u>

$\Delta kW = (\# of replaced fixtures) * (Watts_b)$
(# of fixtures installed) * $(Watts_q) = (LPD_b - LPD_q) * (SF)$

Energy Savings  $\left(\frac{kWh}{yr}\right) = (\Delta kW) * (Hrs) * (1 + HVAC_e)$ 

Peak Demand Savings (kW) =  $(\Delta kW) * (CF) * (1 + HVAC_d)$ 

\_Fuel Savings 
$$\left(\frac{MMBtu}{vr}\right) = (\Delta kW) * (Hrs) * (HVAC_g)$$

Definition of Variables

Algorithms

Demand Savings =  $\Delta kW \times CF \times (1+IF)$ 

Energy Savings = AkW X EFLH X (1+IF)

 $\Delta kW = (LPD_{base} - LPD_{inst}) X SF$ 

**Definition of Variables** 

 $\frac{AkW}{LPD_{base}} = Change in connected load from baseline to efficient lighting level.$   $\frac{LPD_{base}}{Watts_{b,q}} = Wattage of existing baseline and qualifying equipment$   $LPD_{b} = Baseline lighting power density in Watt per square foot of space floor$ 

area, based on ASHRAE 90.1 Table 9.6.1 (Space-by-Space Method)

LPD<sub>inst</sub> LPD<sub>g</sub> = Lighting power density of <u>installedqualified</u> fixtures, equal to the sum of installed fixture wattage divided by floor area of the space where the fixtures are installed. Wattage of installed fixtures is based on table at <u>http://www.see.com/NR/rdonlyres/FC51087D-2848-42DF-A52A-</u> BDBA1A09BF8D/0/SCE\_B\_StandardFixtureWatts010108.pdf.

SF <del>= space</del> = <u>Space</u> floor area, <del>Square Foot</del>in square feet

### **Prescriptive Lighting**

This is a fixture replacement program for existing commercial customers targeted for facilities performing efficiency upgrades to their lighting systems.

The baseline for linear and U bend fluorescent measures is standard T8 fixtures with electronic ballasts or actual existing HID fixtures.

The baseline for LED fixtures is the actual fixture being replaced.

The baseline for induction lighting is an equivalent pulse start metal halide fixture (6).

The baseline for LED refrigerator Case Lighting is that the fixture replaced was 2.63 times the wattage of the replacement LED (7).

New fixtures and technologies available after publication will be periodically updated. Baselines will be established based on the guidelines noted below.

### <u>Algorithms</u>

Algorithms

Demand Savings =  $(\Delta kW) \times (CF) \times (1 + IF)$ 

Energy Savings =  $(\Delta kW) \times (1 + IF) \times (EFLH)$ 

AKW = (Number of fixtures installed X baseline wattage for new fixture) – (number of replaced fixtures X wattage from table)

\*For refrigerated case LED fixtures, the following protocols will be applied to account for the lighting and refrigeration energy savings associated with this measure.\*

Algorithms	•	Formatted: Heading 4

### **Refrigerated Case LED Lights**

This measure includes the installation of LED lamps in commercial display refrigerators, coolers or freezers. The display lighting in a typical cooler or freezer add to the load on that unit by increasing power consumption of the unit when the lamp is on, and by adding heat to the inside of the unit that must be overcome through additional cooling.

Replacing fluorescent lamps with low heat generating LEDs reduces the energy consumption associated with the lighting components and reduces the amount of waste heat generated from the lamps that must be overcome by the unit's compressor cycles.

## **Specialty LED Fixtures**

Some LED fixtures do not adhere to the Prescriptive Lighting algorithm due to unique form factors that do not lend to a fixture-to-fixture comparison, such as LED rope lights, cove lighting, and so on.

In these instances, a similar algorithm may be used, with a different metric other than fixture quantity entered. For example, a comparison of watts per linear foot between LED and incandescent technologies would result in accurate energy savings calculations.

Formatted: Right: 0"

<u>Algorithms</u>

 $\Delta kW =$ 

(linear feet of replaced cove lighting) \*
(baseline fixture wattage of cove lighting per foot)\_
(linear feet of installed LED cove lighting) \*
(wattage of new LED cove lighting per foot)

Energy Savings 
$$\left(\frac{kWh}{yr}\right) = (\Delta kW) * (1 + HVAC_e) * (Hrs)$$

Peak Demand Savings (kW) =  $(\Delta kW) * (CF) * (1 + HVAC_d)$ 

Fuel Savings 
$$\left(\frac{\text{MMBtu}}{\text{yr}}\right) = (\Delta kW) * (\text{Hrs}) * (\text{HVAC}_g)$$

## Electronically Commutated Motors for Refrigeration

This measure is applicable to existing walk-in, multi-deck and free standing coolers and freezers with shaded pole or permanent split capacitor (PSC) motors. -These fractional horsepower motors are significantly more efficient than mechanically commutated, brushed motors, particularly at low speeds or partial load. -By employing variable-speed technology, EC motors are able to optimize fan speeds for changing load requirements. Because these motors are brushless and utilize DC power, losses due to friction and phase shifting are eliminated. -Calculations of savings for this measure take into account both the increased efficiency of the motor as well as the reduction in refrigeration load due to motor heat loss.

#### Electric HVAC Systems

The measurement of This measure provides energy and demand savings for C/I Efficient HVAC program for Room AC, Central AC, and air cooled DX is based on algorithms. (Includes for C&I Electric HVAC systems. The type of systems included in this measure are: split systems, single package systems, air to air cooled heat pumps, packaged terminal systems, (PTAC and PTHP), single package vertical systems, (SPVAC and SPVHP), central DX AC systems, water source heat pumps, ground water source heat pumps, and/or ground source heat pumps).

This measure applies to new construction, replacement of failed equipment, or end of useful life. The baseline unit is a code compliant unit with an efficiency as required by ASHRAE Std. 90.1 – 2013, which is the current code adopted by the state of New Jersey.

Definition of Variables	
$\frac{\text{BtuH} = \text{Cooling}N}{\text{M}} = \text{Number of units}$	
<u>Tons</u> = <u>Rated cooling</u> capacity <u>in Btu/Hour</u> <u>of unit</u> . This value comes fro ARI/AHRI or AHAM rating or manufacturer data.	<b>Formatted:</b> Indent: Left: 0.25", Space Before: 3 pt, After: 3 pt
$EER_{b}$ = Energy Efficiency Ratio of the baseline unit. This data is found in and Heat Pumps table belowFor units < 65,000 BtuH <sub>7</sub> (5.4 tons), SEER shused in place of EER.	Before: 3 nt Atter: 3 nt
New Jersey's Clean Energy Program	Page 122

Protocols to Measure Resource Savings

Formatted: Space Before: 6 pt, After: 6 pt

$COP_b$ = Coefficient of Performance of the baseline unitThis data is found in the HVAC and Heat Pumps table belowFor units < 65,000 BtuH <sub>7</sub> (5.4 tons), SEER and HSPF/3.412 should be used in place of COP $\times$ * 3.412 for cooling and heating savings, respectively.	<b>Formatted:</b> Indent: Left: 0.25", Space Before: 3 pt, After: 3 pt
$EER_q$ = Energy Efficiency Ratio of the high efficiency unit. This value comes from $\checkmark$ the ARI/AHRI or AHAM directories or manufacturer data. For units < 65,000 (5.4 tons) BtuH, SEER should be used in place of EER.	Formatted: Indent: Left: 0.25", Space Before: 3 pt, After: 3 pt
$COP_q$ = Coefficient of Performance of the high efficiency unit. This value comes from the ARI/AHRI or AHAM directories or manufacturer dataFor units < 65,000 BtuH <sub>57</sub> (5.4 tons), SEER and HSPF/3.412 should be used in place of COP X* 3.412 for cooling and heating savings, respectively.	Formatted: Indent: Left: 0.25", Space Before: 3 pt, After: 3 pt
CF = Coincidence Factor – This value represents the percentage of the total load which is on during electric system's Peak WindowThis value will beis based on existing measured usage and determined as the average number of operating hours during the peak window period.	Formatted: Indent: Left: 0.25", Space Before: 3 pt, After: 3 pt
<b>EFLH</b> - <u>EFLH<sub>e or h</sub></u> = Equivalent Full Load Hours – This represents a measure of energy use by season during the on-peak and off peak periods. This value will be determined by existing measured data of kWh during the period divided by kW at design conditions-peak periods.	Formatted: Indent: Left: 0.25", Space Before: 3 pt, After: 3 pt

<u>Dual Enthalpy Economizers</u> <u>Algorithms</u>	
Energy Savings (kWh) = OTF * *SF * *Cap/Eff	
Demand Savings (kW) = Savings/Operating Hours	Formatted: Font: Bold, Font color: Black
Definition of Variables	
OTF = Operational Testing Factor	
SF = Approximate savings factor based on regional temperature bin data (assume 4576	
for equipment under 5.4 tons where a fixed damper is assumed for the baseline and 3318	
for larger equipment where a dry bulb economizer is assumed for the baseline). (Units	
for savings factor are in kWh x rated EER per ton of cooling or kWh*EER/Ton)	
Cap = Capacity of connected cooling load (tons)	
New Jersey's Clean Energy Program Page 129	
Protocols to Measure Resource Savings	

#### Eff = Cooling equipment energy efficiency ratio (EER)

#### Operating Hours = 4,438 = Approximate number of economizer operating hours

#### **Dual Enthalpy Economizers**

The following algorithm details savings for dual enthalpy economizers. They are to be used to determine electric energy savings between baseline standard units and the high efficiency units promoted in the program. The baseline condition is assumed to be a rooftop unit with fixed outside air (no economizer). The high efficiency units are equipped with sensors that monitor the enthalpy of outside air and return air and modulate the outside air damper to optimize energy performance.

Algorithms

Electric energy savings  $(kWh/yr) = N * Tons * (\Delta kWh/ton)$ 

<u>Peak Demand Savings (kW) =  $0^{44}$  kW</u>

**Definition of Variables** 

N = Number of units

Tons= Rated capacity of the cooling system retrofitted with an economizer $\Delta kWh/ton$ = Stipulated per building type electricity energy savings per ton of<br/>cooling system retrofitted with an economizer

Summary of Inputs

### **Dual Enthalpy Economizers**

Component	Туре	Value	Source •
N	Variable		Application
Tons	<u>Variable</u>	Rated Capacity,	Application
		Tons	
<u>AkWh/ton</u>	Fixed	See Table Below	<u>1</u>

Savings per Ton of Cooling System		
	<b>Building Type</b>	Savings (AkWh/ton)
	Assembly	<u>27</u>

<sup>44</sup> Economizer savings occur when outdoor air enthalpy is relatively low, and these conditions mostly exist outside of defined system peak demand periods, therefore, the seasonal peak demand savings for this measure are assumed to be negligible.

<b>Occupancy Controlled Thermostats</b> The program has received a large amount of custom electric applications for the installation of Occupancy Controlled Thermostats in hotels, motels, and, most recently, university dormitories. Standard practice today is thermostats which are manually controlled by occupants to regulate temperature within a facility. An occupancy controlled thermostat is a thermostat paired with a sensor and/or door detector to identify movement and determine if a room is occupied or unoccupied. If occupancy is sensed by the sensor, the thermostat goes into an occupied mode (i.e., programmed setpoint). If a pre-programmed time frame elapses (i.e., 30 minutes) and no occupancy is sensed during that time, the thermostat goes into an unoccupied mode (e.g., setback setpoint or off) until occupancy is sensed again. This type of thermostat is often used in hotels to conserve energy. The occupancy controlled thermostat reduces the consumption of electricity and/or gas by requiring less heating and/or cooling when a room or a facility is vacant or unoccupied. Algorithms Cooling Energy Savings (kWh/yr) = (T <sub>k</sub> - ((T <sub>h</sub> * (H+5) + S <sub>n</sub> * (168 - (H+5)))/168) - T <sub>c</sub> )* (P <sub>a</sub> * Cap <sub>th</sub> * 12 * EFLH <sub>2</sub> /EER <sub>thp</sub> ) Heating Energy Savings (kWh/yr) = (T <sub>k</sub> - ((T <sub>h</sub> * (H+5) + S <sub>h</sub> * (168 - (H+5)))/168))* (P <sub>b</sub> * Cap <sub>th</sub> * 12 * EFLH <sub>2</sub> /EER <sub>thp</sub> ) Heating Energy Savings (Therms/yr) = (T <sub>h</sub> - ((T <sub>h</sub> * (H+5) + S <sub>h</sub> * (168 - (H+5)))/168) * (P <sub>b</sub> * Cap <sub>th</sub> * EFLH <sub>2</sub> /AFUE <sub>2</sub> /100,000) Definition of Variables T <sub>h</sub> = Heating Season Facility Temp. ## **Electric Chillers**

The measurement of energy and demand savings for C&I chillers is based on algorithms with key variables (i.e., kW/ton, Coincidence Factor, Equivalent Full Load Hours) measured through existing end-use metering of a sample of facilities.	<b>Formatted:</b> Right: -0.13", Space Before: 6 pt, After: 6 pt
This measure applies to new construction, replacement of failed equipment, or end of useful life. The baseline unit is a code compliant unit with an efficiency as required by ASHRAE Std. $90.1 - 2013$ , which is the current code adopted by the state of New Jersey.

#### Variable Frequency Drives

The measurement This section provides algorithms and assumptions for reporting of energy and demand savings for C/I Variable Frequency Drive for (VFD applications is are for constant and variable air volume system) installations for HVAC systems including: supply air fans, return air fans, chilled water and condenser water pumps, hot water circulation pumps, water source heat pump circulation pumps, cooling tower fans, kitchen hood fans, and boiler feed water pumps, and boiler draft fans only... VFD applications for other than this useend uses should follow the custom path.

The ESF for the supply and return fans and circulating pumps are derived from a 2014 NEEP-funded study of 400 VFD installations in eight northeast states. The derived values are based on actual logged input power data and reflect average operating hours, load factors, and motor efficiencies for the sample. Savings factors representing cooling tower fans and boiler feed water pumps are not reflected in the NEEP report. Values representing these applications are taken from April 2018 New York TRM, Appendix K, and represent average values derived from DOE2.2 simulation of various building types and climate zones, supplemented with results from an earlier analysis of actual program data completed by NSTAR in 2010.

The DSF are derived from the same sources. The NEEP values reflect the actual average impact for the category occurring in the PJM defined peak demand period. The NY values are based on a similar but not identically defined peak period. In all cases the values are expressed in kW/HP rating of the controlled motor and reflect average load factors during the peak period and motor efficiencies for the sample.

Variable Speed Air Compressors with Variable Frequency Drives This measure applies to the installation of variable speed air compressors in retrofit installations where they replace fixed speed compressor with either inlet vane modulation, load no load, or variable displacement flow control. The measure also applies to "lost opportunity" installations including new construction, the expansion of existing facilites, or replacement of existing equipment at end of life. In all cases the baseline is assumed to be a fixed speed compressor with one of the flow control methods described above.

The measure applies to variable speed air compressor up to 75 HP. For larger installations, the implementation cost and energy savings varies significantly between installations and the deemed savings factors provided here are not applicable. Custom protocols should be applied to derive savings and incentive levels for installations larger than 75 HP.

<u>Algorithms</u>

The measurement of energy and demand savings for variable frequency drive (VFD) air compressors.

#### Algorithms

Energy Savings (kWh/yr) = HRS \* (\*(Maximum kW/HP Savings) \* )\*Motor HPSF \* HP • \* 0.746

<u>Peak</u> Demand Savings (kW) = <u>PDC \* (\*(Maximum kW/HP Savings) \* )\*Motor</u> <u>HPHP \* CF \* 0.746</u>

Maximum kW/HP Savings = Percent Energy Savings \* (0.746 / EFF<sub>b</sub>)

**Definitions** Definition of Variables

HRS\_\_\_\_ = Annual compressor runtime (hours)-run time from application-, (hours/year).

PDC = Peak Duty Cycle: fraction of time the compressor runs during peak hours

EEF<sub>b</sub> = Efficiency of the industry standard compressor at average load

0.746 = kW to HP conversion = Conversion factor = HP to kW

Kitchen Hoods with Variable Frequency Control utilize optical and temperature sensors at the hood inlet to monitor cooking activity. -Kitchen hood exhaust fans are throttled in response to real time ventilation requirements.- Energy savings result from fan power reduction during part load operation as well as a decrease in heating and cooling requirement of make-up air.

## <u>Aluminum Night Covers</u>

This measure is applicable to existing open-type refrigerated display cases where considerable heat is lost through an opening that is directly exposed to ambient air. These retractable aluminum woven fabric covers provide a barrier between the contents of the case and the outside environment. They are employed during non-business hours to significantly reduce heat loss from these cases when contents need not be visible.

Savings approximations are based on the report, "Effects of the Low Emissivity Shields on performance and Power use of a refrigerated display case," by Southern California Edison, August 8, 1997. Southern California Edison (SCE) conducted this test at its stateof-the-art Refrigeration Technology and Test Center (RTTC), located in Irwindale, CA. The RTTC's sophisticated instrumentation and data acquisition system provided detailed tracking of the refrigeration system's critical temperature and pressure points during the test period. These readings were then utilized to quantify various heat transfer and power related parameters within the refrigeration cycle. The results of SCE's test focused on three typical scenarios found mostly in supermarkets: low, medium and high temperature cases.

#### Algorithms

Energy Savings (kWh/yr) = W \* H \* F

#### **Definition of Variables**

- W = Width of protected opening in ft.
- <u>H</u> = Hours per year covers are in place
- <u>F</u> = Savings factor based on case temperature

Summary of Inputs

Aluminum	Night (	Covers -	Commercial	Refrigeration
Alummum	1 AIght	COVERS -	Commercial	Rungulation

<b>Component</b>	Type	Value	<b>Source</b>
W	Variable		<u>Application</u>
<u>H</u>	<u>Variable</u>		Application

#### Walk-in Cooler/Freezer Evaporator Fan Control

This measure is applicable to existing walk-in coolers and freezers that have evaporator fans which run continuously. The measure adds a control system feature to automatically shut off evaporator fans when the cooler's thermostat is not calling for cooling. The measurement of energy savings for this measure is based on algorithms with key variables provided by manufacturer data or prescribed herein. These savings take into account evaporator fan shut off and associated savings as a result of less heat being introduced into the walk-in, as well as the savings from the compressor, which is now being controlled through electronic temperature control.

Several case studies have been performed that verify the accuracy of these savings. The algorithms below are based on field-tested approximations of energy savings realized through installation of National Resource Management Inc. (NRM)'s Cooltrol® energy management system.<sup>49</sup>

#### Algorithms

<u>Gross Energy Savings (kWh/yr) = kWh Savings<sub>EF</sub> + kWh Savings<sub>RH</sub> + kWh Savings<sub>EC</sub></u>

<u>kWh SavingsEF = ((Amps<sub>EF</sub> \* Volts<sub>EF</sub> \* (Phase<sub>EF</sub>)<sup>1/2</sup>)/1000) \* 0.55 \* 8,760 \* 35.52%</u>

<u>kWh SavingsRH = kWh Savings<sub>EF</sub> \* 0.28 \* 1.6</u>

 $\frac{kWh \ SavingsEC = (((Amps_{CP} * Volts_{CP} * (Phase_{CP})^{1/2})/1000) * 0.85 * ((35\% * WH) + ((55\% * NWH)) * 5\%) + (((Amps_{EF} * Volts_{EF} * (Phase_{EF})^{1/2})/1000) * 0.55 * 8,760 * (35\% * 5\%))$ 

<u>Gross kW Savings = ((Ampser \* Voltser \* (Phaser)<sup>1/2</sup>)/1000) \* 0.55 \* D</u>

#### Definition of Variables

<u>kWh Savings<sub>EF</sub></u>	= Savings due to Evaporator Fan being off
<u>kWh Savings<sub>RH</sub></u>	= Savings due to reduced heat from Evaporator Fans
<u>kWh Savings<sub>EC</sub></u>	= Savings due to the electronic controls on compressor and
evaporator	
Amps <sub>EF</sub>	= Nameplate Amps of Evaporator Fan
<u>Volts<sub>EF</sub></u>	= Nameplate Volts of Evaporator Fan
Phase <sub>EF</sub>	= Phase of Evaporator Fan
0.55	<u>= Evaporator Fan Motor power factor</u>
<u>8,760</u>	= Annual Operating Hours

## Novelty Cooler Shutoff

This measure is applicable to existing reach-in novelty coolers which run continuously. The measure adds a control system feature to automatically shut off novelty coolers based on pre-set store operating hours. Based on programmed hours, the control mechanism shuts off the cooler at end of business, and begins operation on reduced cycles. Regular operation begins the following day an hour before start of business. The measurement of energy savings for this measure is based on algorithms with key variables provided by manufacturer data or prescribed herein.

Several case studies have been performed that verify the accuracy of these savings. The algorithms below are based on field-tested approximations of energy savings realized through installation of National Resource Management Inc. (NRM)'s Cooltrol® energy management system.<sup>52</sup>

#### <u>Algorithms</u>

Energy Savings (kWh/yr) = (((Amps<sub>NC</sub> \* Volts<sub>NC</sub> \* (Phase<sub>NC</sub>)<sup>1/2</sup>)/1000) \* 0.85) \* ((0.45 \* ((CH - 1) \* 91)) + (0.5 \* ((CH - 1) \* 274)))

## **Definition of Variables**

<u>Amps<sub>NC</sub> =</u>	= Nameplate A	Amps of N	Jovelty	Cooler

<u>Volts<sub>NC</sub> = Nameplate Volts of Novelty Cooler</u>

<u>Phase<sub>NC</sub> = Phase of Novelty Cooler</u>

0.85 = Novelty Cooler power factor

0.45 = Duty cycle during winter month nights

CH = Closed Store hours

91 = Number of days in winter months

0.5 = Duty cycle during non-winter month nights [3]

274 = Number of days in non-winter months

## **Food Service Measures Protocols**

Energy efficient electric or natural gas cooking equipment of the following listed types utilized in commercial food service applications which have performance rated in accordance with the listed ASTM standards:

- Electric and gas combination oven/steamer ASTM F2861
- Gas convection ovens ASTM F1496
- Gas conveyor ovens ASTM F1817
- Gas rack ovens ASTM F2093
- Electric and gas small vat fryers ASTM F1361
- Electric and gas large vat fryers ASTM F2144
- Electric and gas steamers ASTM F1484
- Electric and gas griddles ASTM F1275
- Hot food holding cabinets -CEE Tier II
- <u>Commercial dishwashers ENERGY STARRefrigerators, Freezers –</u> <u>ENERGY STAR</u>
- Ice Machines ARI Standard 810

### **Electric and Gas Combination Oven/Steamer**

<u>The measurement of energy savings for this measure is based on algorithms with key</u> variables provided by manufacturer data or prescribed herein.

### <u>Algorithms</u>

Energy Savings (kWh/yr or Therms/yr) =  $D^*(E_p + E_{ic} + E_{is} + E_{cc} + E_{cs})$ 

Peak Demand Savings (kW) = kWh Savings/(D\*H)

<u>Preheat Savings<sup>†</sup>:  $E_p = P^*(PE_b - PE_q)$ </u>

Convection Mode Idle Savings<sup>†</sup>:  $\underline{E}_{ic} = (\underline{I}_{cb} - \underline{I}_{cq})^*((\underline{H} - (\underline{P}^*\underline{P}_t)) - (\underline{I}_{cb}/\underline{PC}_{cb} - \underline{I}_{cq})^*(\underline{I}_{cd} - \underline{I}_{cq})^*(\underline{I}_{cd} - \underline{I}_{cd})^*(\underline{I}_{cd}  

Steam Mode Idle Savings<sup>†</sup>:  $\underline{E}_{is} = (I_{sb} - I_{sq})^*((H - (P^*P_t)) - (I_{sb}/PC_{sb} - I_{sq})^*(I_{sb})^*S_t$ 

<u>Convection Mode Cooking Savings:  $E_{cc} = Lbs^*(1-S_t)^*Heat_c^*(1/Eff_{cb} - 1/Eff_{ca})/C$ </u>

New Jersey's Clean Energy Program Protocols to Measure Resource Savings

Formatted: Tab stops: 1.03", Left

Formatted: Indent: First line: 0.25"

Formatted: Indent: Left: 0.25"

Formatted: Heading 4

<u>Steam Mode Cooking Savings:  $E_{cs} = Lbs*S_t*Heat_s*(1/Eff_{sb} - 1/Eff_{sq})/C</u></u>$ 

 $\pm$  – For gas equipment, convert these intermediate values to therms by dividing the result by 100,000 Btu/therm

**Definition of Variables**

#### <u>Electric and Gas Convection Ovens, Gas Conveyor and Rack Ovens, Steamers, Fryers,</u> <u>and Griddles</u>

The measurement of energy savings for these measures are based on algorithms with key variables provided by manufacturer data or prescribed herein.

Algorithms

Energy Savings (kWh/yr or Therms/yr) =  $D * (E_p + E_i + E_c)$ 

<u>Peak</u> Demand Savings (kW) = kWh Savings / (D \* H)

<u>Preheat Savings<sup>†</sup>:  $E_p = P * (PE_b - PE_q)$ </u>

Idle Savings<sup>†</sup>:  $\underline{E}_i = (\underline{I}_b - \underline{I}_q) * ((\underline{H} - (\underline{P} * \underline{P}_t)) - (\underline{I}_b / \underline{P} \underline{C}_b - \underline{I}_q / \underline{P} \underline{C}_q) * \underline{L} \underline{b} \underline{s})$ 

Cooking Savings:  $E_c = Lbs * Heat * (1/Eff_b - 1/Eff_q) / C$ 

 $\pm$  – For gas equipment, convert these intermediate values to therms by dividing the result by 100,000 Btu/therm

**Definition of Variables**

## Commercial Dishwashers

This measure is applicable to replacement of existing dishwashers with energy efficient under counter, door type, single-rack and multi-rack conveyor machines testing in accordance with NSF/ANSI 3-2007, ASTM F1696, and ASTM F1920 standards. The measurement of energy savings for this measure is based on algorithms with key variables provided by manufacturer data or prescribed herein.

## <u>Algorithms</u>

Energy Savings (kWh/yr or Therms/yr) =  $E_{Build} + E_{Boost} + E_{Idle}$ 

Peak Demand Savings (kW) = kWh Savings/8760

<u>Note: Depending on water heating system configuration (e.g. gas building water heater</u> <u>with electric booster water heater), annual energy savings may be reported in both therms</u> <u>and kWh.</u>

**Definition of Variables** 

EER	Fixed	<del>9.0</del>	Average based on custom
			applications for the NJCEP
			C&I Program in 2010
Usage	Fixed	<del>8,760</del>	<del>365 days/year, 24</del>
			hours/day

(See tables below for more information)<sup>56</sup>

 $\underline{E_{Build}}$  = Annual Building Water Heater Energy Savings, in kWh or Therms (from tables below)

 $\underline{E}_{Boost}$  = Annual Booster Water Heater Energy Savings, in kWh or Therms (from tables below)

 $\underline{E_{\text{Idle}}}$  = Annual Dishwasher Idle Energy Savings, in kWh (from tables below) 8760 = Hours per Year

Summary of Inputs

<sup>56</sup> Savings algorithm, baseline values, assumed values and lifetimes developed from information on the Food Service Technology Center program's website, www.fishnick.com, by Fisher-Nickel, Inc. and funded by California utility customers and administered by Pacific Gas and Electric Company under the auspices of the California Public Utility Commission and from the Savings Calculator for ENERGY STAR Qualified Commercial Kitchen Equipment.

#### **Commercial Refrigerators and Freezers**

This measure is applicable to replacement of existing commercial grade refrigerators and freezers with energy efficient glass and solid door units complying with ANSI/ASHRAE Standard 72-2005, Method of Testing Commercial Refrigerators and Freezers. -The measurement of energy savings for this measure is based on algorithms with key variables provided by manufacturer data or prescribed herein.

**Algorithms** 

Annual

<u>Algorithms</u>

Energy Savings  $(kWh/yr) = D * (E_b - E_q)$ 

<u>Peak</u> Demand Savings (kW) = kWh Savings/ (D \* H)

Definition of Variables

(See tables below for more information)<sup>57</sup>

D\_= Operating Days per Year (assume 365)

H\_= Daily Operating Hours (assume 24)

 $E_b$  = Daily kWh Consumption of Baseline Equipment (from Table 1 below)

E<sub>q</sub> = Daily kWh Consumption of Qualifying Equipment (from Application)

Table 1: Baseline I	Equipment Daily kWh Consumption
Proposed Equipment Type	<i>kWh Consumption</i> ( $V = Unit Volume in ft3$ )
Glass Door Freezer	0.75V + 4.1
Glass Door Refrigerator	0.12V + 3.34
Solid Door Freezer	0.4V + 1.38
Solid Door Refrigerator	0.1V + 2.04

#### Summary of Inputs

Table 1: Baseline I	Equipment Daily kWh Consumption
Proposed Equipment Type	kWh Consumption ( $V = Unit$ Volume in $ft^3$ )
Glass Door Freezer	0.75V + 4.1
Glass Door Refrigerator	0.12V + 3.34
Solid Door Freezer	0.4V + 1.38
Solid Door Refrigerator	0.1V + 2.04

#### **Commercial Ice Machines**

This measure is applicable to replacement of existing ice makers with energy efficient, air-cooled ice machines tested in accordance with ARI Standard 810. The measurement of energy savings for this measure is based on algorithms with key variables provided by manufacturer data or preseribed herein.

#### Algorithms

Annual Energy Savings (kWh) =  $D * DC * (IHR/100) * (E_b - E_q)$ 

Demand Savings (kW) = kWh Savings / (D \* 24 \* DC)

**Definition of Variables** 

D = Operating Days per Year (assume 365)

DC = Duty Cycle, defined as Ice Harvest Rate/Actual Daily Ice Production (assume 75%)

IHR = Proposed Equipment Ice Harvest Rate in lbs/day (from Application)

- $E_b = kWh$  Consumption of Baseline Equipment in kWh/100 lbs (from Table 1 below)
- $E_q = kWh$  Consumption of Qualifying Equipment in kWh/100 lbs (from Application)

24 = Hours per Day

Table 1: B	Saseline Energy Consumption
Ice Harvest Rate (lbs/day)	Baseline Energy Consumption (kWh/100 lbs)

	Gas Fired <del>Desiccants<u>Dessicants</u></del>		Formatted: Page break before
	Gas-fired desiccant systems employ a desiccant wheel (a rotating disk filled with a dry desiccant such as silica gel, titanium gel, or dry lithium chloride) which adsorbs outside air moisture, reducing the air's latent heat content This air is then conditioned by the building's cooling system, before being delivered to the occupied space By reducing the relative humidity of the air, the operating temperature of the building can be increased, as comfort levels are maintained at higher temperatures when air moisture content is decreased Electric savings are realized from a reduction in the required cooling load as a result of decreased humidity.		Formatted: Space Before: 6 pt, After: 6 pt
	In order to maintain the usefulness of the desiccant (to keep it dry) hot air must be passed through the desiccant that has been used to remove moisture from the outside air To supply this hot air, a gas-fired heater is employed to heat "regeneration" air, which picks up moisture from the saturated desiccant and exhausts it to the outside As a result, in addition to electric benefits, these systems will also incur a natural gas penalty		<b>Formatted:</b> Space Before: 6 pt, After: 6 pt
1	Electric savings and natural gas consumption will vary significantly from system to system depending on regional temperature and humidity, facility type, occupancy, site processes, desiccant system design parameters, ventilation requirements and cooling load and system specificationsDue to the multitude of site and equipment specific factors, along with the relative infrequency of these systems, gas-fired desiccant systems will be

Stand Alone Storage Water Heaters		
This prescriptive measure targets solely the use of smaller scale domestic is intended for stand alone storage water heaters (50 gallons or less per unit)installed in all-commercial facilities. Larger gasThe savings algorithms are based on installed equipment specifications and data from the Commercial Building Energy Consumption Survey (CBECS).		
Baseline efficiencies are set by current and previous equipment performance standards. In New Jersey ASHRAE 90.1 defines the commercial energy code requirements. For new buildings, ASHRAE 90.1-2013 standards apply, and for existing buildings, ASHRAE 90.1-2007 standards are assumed.		
Note, that forstand alone storage water heaters are treated under the custom measure path. The measurement with a rated input capacity greater than 75 kBtu/hr, equipment standards are defined in terms of thermal efficiency. Equipment below this input capacity		Formatted: Normal, Space Before: 6 pt, After: 6 pt
is rated in terms of energy savings for C&I gas water heaters is based on algorithms with key variables (i.e., energy-factor) provided by manufacturer data. Energy factor is determined on a 24 hour basis and includes standby or storage loss effects, while thermal efficiency does not. Therefore, if the equipment is large enough to be rated in terms of thermal efficiency, a percent standby loss factor must be included in the calculation as shown in the algorithms.

Public assembly	<u>2.1</u>
Public order and safety	<u>21.4</u>
Religious worship	<u>0.9</u>
Service	<u>15</u>
Warehouse and storage	<u>2.9</u>
Other	<u>2.3</u>

Example: If a water heater of 150 kBtu/hr input capacity and 100 gallons storage capacity is installed in an existing building, the baseline standby losses would be calculated as SL =  $(150 \text{ kBtu/hr} / 0.8 + 110 \times \sqrt{100}) / 1000 = 1.29 \text{ kBtu/hr}$ . If the proposed equipment's standby losses were rated for 1.0 kBtu/hr, the standby loss factor for savings would be SLF = (1.29 - 1.0) / 150 = 0.0019.

In the above example, if the unit was rated for 96% thermal efficiency, and installed in an office building space of 10,000 ft<sup>2</sup>, the annual energy savings would be  $((1 - 0.8/0.96) + 0.0019) \times 4.8 \times 10000 / 1000 = 8.1 \text{ MMBtus/yr}$

#### Instantaneous Gas Water Heaters

This prescriptive measure is intended for instantaneous water heaters installed in commercial facilities. This measure assumes that the baseline water heater is either a code stand alone storage water heater, or a code instantaneous water heater. The savings algorithms are based on installed equipment specifications and data from the Commercial Building Energy Consumption Survey (CBECS).

Baseline efficiencies are set by current and previous equipment performance standards. In New Jersey ASHRAE 90.1 defines the commercial energy code requirements. For new buildings, ASHRAE 90.1-2013 standards apply, and for existing buildings, ASHRAE 90.1-2007 standards are assumed.

If the qualifying instantaneous water heater is greater than 200 kBtu/hr and replacing a stand alone storage water heater, use a baseline storage water heater efficiency greater than 75 kBtu/hr. Similarly, if the qualifying instantaneous water heater is less than 200 kBtu/hr, and replacing a stand alone storage water heater, use an efficiency for equipment less than 75 kBtu/hr.

New Jersey's Clean Energy Program Protocols to Measure Resource Savings **Formatted:** Sources, No bullets or numbering

Note, that for stand alone storage tank water heaters rated above 75 kBtu/hr, and instantaneous water heaters above 200 kBtu/hr, equipment standards are defined in terms of thermal efficiency. Equipment below these levels is rated in terms of energy factor. Energy factor is determined on a 24 hour basis and includes standby or storage loss effects, while thermal efficiency does not. Therefore, if the equipment is large enough to be rated in terms of thermal efficiency, a percent standby loss factor must be included in the calculation as shown in the algorithms.

## <u>Algorithms</u>

<u>Fuel Savings (MMBtu/yr) = ((1 – (EFF<sub>b</sub> / EFF<sub>q</sub>) + SLF<sup>61</sup>) \* Energy Use Density \*</u> <u>Area</u>

## Where,

 $\underline{SLF} = 0.775 \times \underline{Cap_q}^{\underline{-0.778}}$ 

## **Definition of Variables**

 $EFF_q = Efficiency$  of the qualifying instantaneous water heater.

 $EFF_b = Efficiency of the baseline water heater, commercial grade.$ 

 $EF_b = Efficiency of the baseline water heater, commercial grade.$ 

<u>SLF</u> = Standby loss factor of the baseline water heater fuel usage. This was calculated from standby loss and input capacity data for commercial water heaters exported from the AHRI database.

Energy Use Density = Annual baseline water heater energy use per square foot of commercial space served (MMBtu/sq.ft./yr)

<u>Area = Square feet of building area served by the water heater</u>

 $Cap_q = Rated$  input capacity of the qualifying water heater

**Distributed Energy Resource (DER)** 

New Jersey's Clean Energy Program Protocols to Measure Resource Savings

Page 208

# Combined Heat & Power Program

## **Protocols**

The measurement of energy and demand savings for Combined Heat and Power (CHP)/fuel cell) systems is based primarily on the characteristics of the individual systems subject to the general principles set out below. -The majority of the inputs used to estimate energy and demand impacts of CHP/fuel cell\_systems will be drawn from individual project applications. Eligible systems include: powered by non-renewable or renewable fuel sources, gas internal combustion engine, gas combustion turbine, microturbine, and fuel cells with heat recovery.

<u>CHP/fuel cell</u><u>The NJ Protocol is to follow the National Renewable Energy Laboratory's</u> Combined Heat and Power, The Uniform Methods Project: Methods for Determining Energy-Efficiency Savings for Specific Measures [1]. The product should be all of the below outputs, as applicable:

- a. Annual energy input to the generator, HHV basis (MMBtu/yr)
- b. Annual electricity generated, net of all parasitic loads (kWh/yr)
- c. Annual fossil fuel energy savings from heat recovery (MMBtu/yr)
- d. Annual electric energy savings from heat recovery, including absorption chiller sourced savings if chiller installation is included as part of the system installation (kWh/yr)
- e. Annual overall CHP fuel conversion efficiency, HHV basis (%)
- f. Annual electric conversion efficiency, net of parasitics, HHV basis (%)

<u>CHP</u> systems typically use fossil fuels to generate electricity that displaces electric generation from other sources. Therefore, the electricity generated from a CHP/fuel cell system should not be reported as either electric energy savings or renewable energy generation. -Alternatively, electric generation and capacity from CHP/fuel cell systems should be reported as Distributed Generation (DG) separate from energy savings and renewable energy generation. -However, any waste heat recaptured and utilized should be reported as energy savings as<sub>7</sub> discussed below.

#### Distributed Generation

Electric Net Electricity Generation (MWh) = Estimated annual and lifetime electric generation in MWh provided on the project application, as adjusted during the project review and approval process.

<u>Peak Electric Demand (kW) = Electric demand reduction delivered by the CHP system</u> provided on the project application, as adjusted during the project review and approval process.

Formatted: Space Before: 6 pt, After: 6 pt

Formatted: Space Before: 6 pt, After: 6 pt

Formatted: Font: Not Bold

Formatted: Space Before: 6 pt, After: 3 pt

<b>Electric Demand (kW) =</b> Electric capacity of the CHP/fuel cell system in kW <u>Total Fuel</u> Consumption or Fuel Consumed by Prime Mover (MMBtu @HHV) = Total heating value of used by CHP system provided on the project application, as adjusted during the project review and approval process.	Formatted: Space Before: 6 pt, After: 3 pt
Energy Savings <u>Impact</u>	
Gas Energy Savings: or Fuel Offset (MMBtu @HHV): Gas savings should be reported on a consistent basis by all applicants as the reduction in fuel related to the recapture of thermal energy (e.g., reduction in boiler gas associated with the recapture of waste heat from the CHP engine or turbine, or a fuel cell with heat recovery.)	Formatted: Font: Not Bold Formatted: Space Before: 6 pt, After: 6 pt
Electric Energy Savings: or Offset Chiller Electricity Use (MWh): Electric energy	Formatted: Font: Not Bold
savings should be reported only in cases where the recapture of thermal energy from the CHP system is used to drive an absorption chiller that would displace electricity previously consumed for cooling.	Formatted: Space Before: 6 pt, After: 6 pt
Emission Reductions	
For many CHP/fuel cell applications there can be substantial emission benefits due to the superior emission rates of many new CHP engines and turbines as compared to the average emission rate of electric generation units on the margin of the gridHowever, CHP engines and turbines produce emissions, which should be offset against the displaced emissions from the electricity that would have been generated by the grid. <sup>64</sup>	Formatted: Space Before: 6 pt, After: 6 pt
The New Jersey Department of Environmental Protection (DEP) has provided the BPU with emissionElectric and natural gas emissions factors that are presented in the Introduction section of the Protocols and are used to calculate the emission savings from energy efficiency and renewable energy projects These factors should be used to calculate the base emission factors which the CHP system emission factors would be compared toThe emissions from the CHP system would be subtracted from the base emissions to determine the net emission changes as follows:	Formatted: Space Before: 6 pt, After: 6 pt
CHP Emissions FactorsReduction Associated with PJM Grid	Formatted: Heading 3, Left

# **Pay for Performance Program**

#### **Protocols**

The Pay for Performance Program is a comprehensive program targeted at existing commercial and industrial (C&I) buildings that have an average annual peak demand of 200 kW or greater; as well as select multifamily buildings with annual peak demand of 100 kW or greater. -Participants in the Pay for Performance Program are required to identify and implement energy efficiency improvements that will achieve a minimum of 15% reduction in total source energy consumption.savings target.

#### **Energy Savings Requirements**

#### Existing Buildings

Projects For Existing Buildings, projects are required to identify and implement comprehensive energy efficiency improvements that will achieve a minimum of 15% reduction in total source energy consumption as measured from existing energy use. (for existing buildings) and 15% energy cost savings from the current state energy code (for new construction). Further, no more than 50% of the total savings may be derived from lighting measures, Savings may not come from a single measure and no more than 50% of the total savings up to 70% of total projected savings can be considered but the minimum savings required will increase proportionately as demonstrated in the table below For New Construction, including major rehabilitation, projects are required to identify and implement comprehensive energy efficiency measures that achieve a minimum 5% energy cost savings for commercial and industrial buildings, and 15% for multifamily, from the current state energy code.

Existing Buildings projects must include multiple measures, where lighting measures do not exceed 50% of total savings (exceptions apply, see program guidelines). New Construction projects must have at least one measure addressing each envelope, heating, cooling, and lighting systems. Buildings that are not heated (e.g. refrigerated warehouse) or not cooled (e.g. warehouse) will not be required to have a measure addressing the missing building system. Formatted: Font: Bold

Formatted: Centered

Formatted: Space Before: 6 pt, After: 6 pt

Lighting Savings	Minimum Source Energy Target
51%	16%
52%	17%
53%	18%
54%	19%
55%	20%
56%	21%
57%	22%
58%	23%
59%	24%
60%	25%
61%	26%
62%	27%
63%	28%
64%	29%
65%	30%
66%	31%
67%	32%
68%	33%
69%	34%
70%	35%

TheIn both program components, the total package of measures must have at least a 10%, internal rate of return (IRR), and at least 50% of the savings must come from investorowned electricity and/or natural gas. If 50% of the savings does not meet this criteria, then the project must save a minimum of 100,000 kWh or 2,000 therms from investorowned utility accounts.

AnFor Existing Buildings, an exception to the 15% savings requirement will be limited is available to sectors such as manufacturing, pharmaceutical, chemical, refinery, packaging, food/beverage, data center, transportation, mining/mineral, paper/pulp, biotechnology, etc, as well as hospitals. The manufacturing and/or processing loads use should be equal to or greater than approximately 50% of the total metered energy use. Instead of the 15% savings requirement, the project must deliver a minimum energy savings of 100,000 kWh, 350 MMBTU or 4% of total facility consumption, whichever is greater. Exceptions must be pre approved by Market Manager and currently only apply to existing buildings component of program.

#### New Construction and Gut Rehabilitation

Projects are required to identify and implement energy efficiency improvements that will achieve a minimum of 5% energy cost savings for C&I buildings, and 15% for multifamily, as measured from ASHRAE 90.1–2013 baseline. Equivalent performance targets for *ASHRAE Building Energy Quotient (bEQ) As Designed* and ASHRAE 90.1–2013 with Addendum BM are provided in the program guidelines (see Baseline Conditions below).

Each project must have at least one measure addressing each envelope, heating, cooling, and lighting systems. Buildings that are not heated (e.g. refrigerated warehouse) or not

Formatted: Space Before: 6 pt, After: 6 pt

Formatted: Space Before: 6 pt, After: 6 pt

Formatted: Space Before: 6 pt, After: 6 pt

# cooled (e.g. warehouse) will not be required to have a measure addressing the missing building system.

#### **Software Requirements**

In order for a project to qualify for incentives under the Pay for Performance Program, the Partner must create a whole-building energy simulation to demonstrate energy savings from recommended energy efficiency measures, as described in detail in the Simulation Guidelines section of the Pay for Performance Program Guidelines. The primary source for developing the Simulation Guidelines is ASHRAE Guideline 14. Simulation software must be compliant with ASHRAE 90.1 -Section 11 or Appendix G. Examples of allowed tools include eQUEST, HAP, EnergyPlus, Trane Trace, DOE 2.1. Approval for use in LEED and Federal Tax Deductions for Commercial Buildings program may serve as the proxy to demonstrate compliance with the requirement.

# Formatted: Space Before: 9 pt, After: 3 pt **Baseline Conditions Existing Buildings Existing Buildings** Baseline from which energy savings are measured will be based off the most recent twelve12 months of energy use from all sources. Site energy use is converted to source energy use following EPA's site-to-source conversion factors<sup>65</sup>. New Construction Project may establish building baseline in one of two ways: Path 1 — Under this path, the Partner will develop a single energy model representing the proposed project design using prescribed modeling assumptions that follow ASHRAE Building Energy Quotient (bEQ) As-Designed<sup>66</sup> simulation requirements. • Path 2 — Under this option the Partner will develop a baseline building using Formatted: Indent: Left: 0.5", No bullets or numberina ASHRAE 90.1-2013 Appendix G modified by Addendum BM<sup>67</sup>. -(for existing buildings) or current state energy code, such as ASHRAE 90.1 2007 (for new construction). Formatted: Space Before: 9 pt, After: 3 pt **Measure Savings** <sup>65</sup> https://portfoliomanager.energystar.gov/pdf/reference/Source%20Energy.pdf Formatted: Space Before: 3 pt, After: 3 pt <sup>66</sup> http://buildingenergyquotient.org/asdesigned.html <sup>67</sup> Addendum BM sets a common baseline building approach that will remain the same for ASHRAE 90.1-2013 and all future iterations of ASHRAE 90.1, and is roughly equivalent to ASHRAE 90.1-2004. -To comply with ASHRAE 90.1-2013, a proposed building has to have energy cost savings of 11-40% from the Addendum BM baseline, depending on the building type and climate zone. New Jersey's Clean Energy Program Page 215 Protocols to Measure Resource Savings

Formatted: Space Before: 9 pt, After: 3 pt

Measures must be modeled to demonstrate proposed energy/energy cost savings according to Pay for Performance program guidelines, including meeting or exceeding Minimum Performance Standards, or current state or local energy code, whichever is more stringent. Minimum Performance Standards generally align with C&I SmartStart Program equipment requirements.

### **Existing Buildings**

Measures must be modeled within the approved simulation software and modeled incrementally to ensure interactive savings are taken into account.

### New Construction

Measures must be modeled based on the baseline path chosen:

- *Path 1* Modeled within the same proposed design energy model, but as parametric runs or alternatives downgraded to code compliant parameters.
- *Path 2* Modeled as interactive improvements to the ASHRAE 90.1-2013 Appendix G baseline (with Addendum BM accepted).

In the event that a software tool cannot adequately model a particular measure or component, or in cases where Program Manager permits savings calculations outside of the model, projects are required to use stipulated savings calculations as outlined in the Program Guidelines or within these Protocols as applicable. If stipulated savings do not exist within these documents, the Program Maanger will work with the applicant to establish acceptable industry calculations. **Formatted:** Space Before: 3 pt, After: 3 pt, Add space between paragraphs of the same style

#### Measurement & Verification

### **Existing Buildings**

The Program metering requirements are based on the 2010 International Performance Measurement and Verifications Protocol ("IPMVP") and the 2008 Federal Energy Management

Program ("FEMP") M&V Guidelines, Version 3.0. All projects must follow Option D, Calibrated Simulation, as defined by the IPMVP. Calibrated simulation involves the use of computer software to predict building energy consumption and savings from energy-efficiency measures. Options A and B, as defined by the IPMVP, may be used as guidelines for data collection to help create a more accurate model. Additionally, for the existing buildings component, Option C is used to measure actual savings using twelve months of post-retrofit utility data.

#### New Construction

Projects are required to commission all energy efficiency measures. Further, projects are required to complete a benchmark through *EPA's ENERGY STAR Portfolio Manager* to demonstrate operational performance based on the building's first year of operation. Building types not eligible ofor ENERGY STAR Score may demonstrate compliance through *ASHRAE Building Energy Quotient (bEQ) In-Operation.* 

### **Energy Savings Reporting**

Committed energy savings are reported upon approval of the Energy Reduction Plan and are based on modeling results of recommended measures as described above. Installed energy savings are reported upon installation of recommended measures and are based on modeling results. Unless significant changes to the scope of work occurred during construction, installed savings will be equal to committed savings. Verified savings are reported at the end of the performance period (for Existing Buildings) and are based on twelve (12) months of post-retrofit utility bills compared to pre-retrofit utility bills used during Energy Reduction Plan development. For New Construction, verified savings are not currently reportedor at the end of the Commissioning process (for new construction) and may vary from committed/installed savingsreported. Note that only installed savings are reported on New Jersey's Clean Energy Quarterly Financial and Energy Savings Reports.

### **Direct Install Program**

### **Protocols**

This section identifies the protocols for all-measures proposed under the Direct Install Program. This section includes protocols for <u>Several of the</u> measures that are not included in other sections of the Protocols. In addition, for several of the where Direct Install Protocols usesuse algorithms and inputs fromidentical to the "*Commercial and Industrial Energy Efficient Construction*" section of the Protocols, and as such, the user is directed to that section of the Protocols, for the specific protocol. Other measures may have similar algorithms and inputs, but identify different equipment baselines will be used-to reflect the Direct Install includes early retirement. Baseline replacement program where equipment efficiency shown in is replaced as a direct result of the program. For those measures, the applicable baseline tables are included in this section is an estimate of existing equipment efficiency rather than currently available standard efficiency., but the user is directed to the C&I section of the Protocols for algorithms and other inputs.

### Electric HVAC Systems

Replacement of existing electric HVAC equipment with high efficiency units is a proposed measure under the <u>Direct Install Program.</u> (See C&I <u>C&I Energy Efficienct</u> <u>Construction Electric HVAC Systems</u> Protocols)... The <u>Direct Install</u> savings protocol will be the same as previously stated in this document with the exception of the assumption for baseline efficiency. For the Direct Install program, the following values will be used for the variable identified as EER<sub>b</sub>. These age based efficiencies are used in estimating savings associated with the Direct Install Program because as an early replacement program, equipment is replaced as a direct result of the program.

### Default Values for Mechanical System Efficiencies Age-Based

Efficiency baselines are designed to reflect current market practices, which in this case reflect ASHRAE 90.1-2007. For the Direct Install program, the following values will be used for the variable identified as  $SEER_b EER_b COP_b IPLV_b$  and  $HSPF_b$

Source: Based on the 2006 Mortgage Industry National Home Energy Ratings Systems Standards, Table 303.7.1(3) Default Values for Mechanical System Efficiencies (Agebased), RESNET.

NOTE The age based efficiencies in the above table have been interpolated from RESNET standards and current baseline figures utilized in NJ C&I Energy Efficiency Rebate programs. With no equivalent resource available specific to small commercial equipment, these combined resources reflect the closest approximation to typical efficiencies of mechanical equipment present in Direct Install project facilities. The Direct Install program is targeted towards small commercial customers. As such, eligible equipment must not exceed a maximum capacity determined to be commonplace in the small C&I sector. In most cases, these capacity ranges correlate well with equipment certified by AHRI under the designation "Residential".

### Motors [Inactive 2017, Not Reviewed]

Replacement of existing motors with high efficiency units is a proposed measure under the Direct Install Program. (See C&I Construction Motors Protocols). The savings protocol will be the same as previously stated in this document with the exception of the assumption for baseline efficiency. For the Direct Install program, the following values will be used for the variable identified as  $\eta_{base}$ . These efficiencies are used in estimating savings associated with the Direct Install Program because as an early replacement program, equipment is replaced as a direct result of the program. ### Variable Frequency Drives

Installation of variable frequency motor drive systems is a proposed measure under the Direct Install Program. (See C&ICommercial and Industrial Energy Efficient Construction-Motors Protocols)... Because there is no baseline assumption included in the protocols for this measure, the savings protocol will be exactly the same as previously stated in this document.

#### **Refrigeration Measures**

Walk-in Cooler/Freezer Evaporator Fan Control

This measure is applicable to existing walk-in coolers and freezers that have evaporator fans which run continuously. The measure adds a control system feature to automatically shut off evaporator fans when the cooler's thermostat is not calling for cooling. The measurement of energy savings for this measure is based on algorithms with key variables provided by manufacturer data or prescribed herein. These savings take into account evaporator fan shut off and associated savings as a result of less heat being introduced into the walk-in, as well as the savings from the compressor, which is now being controlled through electronic temperature control.

Several case studies have been performed that verify the accuracy of these savings. The algorithms below are based on field-tested approximations of energy savings realized through installation of National Resource Management Inc. (NRM)'s Cooltrol® energy management system.<sup>1</sup>

#### Cooler and Freezer Door Heater Control

This measure is applicable to existing walk-in coolers and freezers that have continuously operating electric heaters on the doors to prevent condensation formation. This measure adds a control system feature to shut off the door heaters when the humidity level is low enough such that condensation will not occur if the heaters are off. This is performed by measuring the ambient humidity and temperature of the store, calculating the dewpoint, and using PWM (pulse width modulation) to control the anti-sweat heaters based on specific algorithms for freezer doors. The measurement of energy savings for this measure is based on algorithms with key variables provided by manufacturer data or prescribed herein.

Several case studies have been performed that verify the accuracy of these savings. -The algorithms below are based on field-tested approximations of energy savings realized through installation of National Resource Management Inc. (NRM)'s Cooltrol® energy management system.<sup>4</sup>

#### Aluminum Night Covers

This measure is applicable to existing open type refrigerated display cases where considerable heat is lost through an opening that is directly exposed to ambient air. These retractable aluminum woven fabric covers provide a barrier between the contents of the case and the outside environment. They are employed during non business hours to significantly reduce heat loss from these cases when contents need not be visible.

Savings approximations are based on the report, "Effects of the Low Emissivity Shields on performance and Power use of a refrigerated display case", by Southern California Edison, August 8, 1997. Southern California Edison (SCE) conducted this test at its state of the art Refrigeration Technology and Test Center (RTTC), located in Irwindale, CA. The RTTC's sophisticated instrumentation and data acquisition system provided detailed tracking of the refrigeration system's critical temperature and pressure points during the test period. These readings were then utilized to quantify various heat transfer and power related parameters within the refrigeration cycle. The results of SCE's test focused on three typical scenarios found mostly in supermarkets: low, medium and high temperature cases.

#### Algorithms

kWh Savings = W \* H \* F

**Definition of Variables** 

#### **Electric Defrost Control**

This measure is applicable to existing evaporator fans with a traditional electric defrost mechanism. This control system overrides defrost of evaporator fans when unnecessary, reducing annual energy consumption. The estimates for savings take into account savings from reduced defrosts as well as the reduction in heat gain from the defrost process.

Independent Testing was performed by Intertek Testing Service on a Walk in Freezer that was retrofitted with Smart Electric Defrost capability. A baseline of 28 cleetric defrosts

#### **LED Lighting for Coolers and Freezers**

This measure is applicable to existing walk in and reach in coolers and freezers with non-LED lighting. LED lighting is not only more efficient, but also provides higher quality lighting for cooler and freezer displays as they are more suited for cold environments. In addition, LEDs have a longer operating life than fluorescents in cooler and freezer applications, which results in reduced life cycle costs. The estimated savings for this measure take into account both reduced wattage of replacement lighting and reduced refrigeration load from lighting heat loss.

#### Algorithms

 $kWh Savings = (((Watts_B - Watts_{LED})/1000) * H) * (1 + (0.28 * 1.6))$ 

kW Savings = ((Watts<sub>B</sub> - Watts<sub>LED</sub>)/1000) \* (1 + (0.28 \* 1.6))

### Novelty Cooler Shutoff

This measure is applicable to existing reach in novelty coolers which run continuously. The measure adds a control system feature to automatically shut off novelty coolers based on pre-set store operating hours. Based on programmed hours, the control mechanism shuts off the cooler at end of business, and begins operation on reduced eycles. Regular operation begins the following day an hour before start of business. The measurement of energy savings for this measure is based on algorithms with key variables provided by manufacturer data or prescribed herein.

Several case studies have been performed that verify the accuracy of these savings. -The algorithms below are based on field tested approximations of energy savings realized through installation of National Resource Management Inc. (NRM)'s Cooltrol® energy management system.<sup>4</sup>

#### Algorithms

 $\frac{\text{kWh Savings} = (((Amps_{NC} * \text{Volts}_{NC} * (Phase_{NC})^{1/2})/1000) * 0.85) * ((0.45 * ((CH - 1) * 91)) + (0.5 * ((CH - 1) * 274)))}{(0.5 * ((CH - 1) * 274)))}$

### Gas Space and Water Heating Measures

#### **Gas Furnaces and Boilers**

Replacement of existing gas, oil, or propane furnaces and and propane water heaters with high efficiency units is a proposed measure under the C&I Energy Efficienct Construction GasHVAC Systems Protocols. The Direct Install savings protocol will be the same as previously stated in this document with the baselines designed to reflect current market practices, which in this case reflect ASHRAE 90.1-2007. These tables are included in the C&I Protocol.

#### **Gas Space Heating Measures**

### **Boilers**

<u>Replacement of existing gas, oil, and propane</u> boilers with high efficiency units is a proposed measure under the <u>Direct Install Program.</u> (See C&I <u>Energy Efficienct</u> Construction <u>GasGasHVAC Systems</u> Protocols)... The <u>Direct Install</u> savings protocol will be the same as previously stated in this document with the exception of the assumption for baseline efficiency. For the Direct Install program, the following values will be used for the variable identified as AFUE<sub>b</sub>. These age-based efficiencies are used in estimating savings associated with the Direct Install Program because as an early replacement program, equipment is replaced as a direct result of the program.

### Default Values for Mechanical System Efficiencies – Age-Based

Efficiency baselines are designed to reflect current market practices, which in this case reflect ASHRAE 90.1-2007. For the Direct Install program, the following values will be used for the variable identified as Eff<sub>b</sub>.

Source: 2006 Mortgage Industry National Home Energy Ratings Systems Standards, Table 303.7.1(3) Default Values for Mechanical System Efficiencies (Age-based), RESNET.

NOTE The age based efficiencies in the above table have been interpolated from RESNET standards and current baseline figures utilized in NJ C&I Energy Efficiency Rebate programs. With no equivalent resource available specific to small commercial equipment, these combined resources reflect the closest approximation to typical efficiencies of mechanical equipment present in Direct Install project facilities. The Direct Install program is targeted towards small commercial customers. As such, eligible equipment must not exceed a maximum capacity determined to be commonplace in the small C&I sector. In most cases, these capacity ranges correlate well with equipment certified by AHRI under the designation "Residential".

### Small Commercial Boilers [Inactive 2017, Not Reviewed]

This section will apply only for boilers that are closed loop and for space heating.

For Boilers that are under 5000 MBtuH use the calculator from the Federal Energy Management Program at: http://www1.eere.energy.gov/femp/technologies/eep\_boilers\_calc.html

### Gas, Oil, and Propane Infrared HeatingFurnaces

Replacement of existing atmospherically vented heating with gas or, oil, and propane infrared heating is an available measure under the Direct Install Program. (See C&I Construction Gas Protocols).

**Gas Water Heating** 

Replacement of existing gas furnaces and boilers-with gas high efficiency units is a proposed measure under the Direct Install Program. (See C&I Energy Efficienct Construction Gas <u>HVAC Systems</u> Protocols)... The Direct Install savings protocol will be

#### Food

Electric

### **Infrared Heating**

Replacement of existing atmospherically vented heating with infrared heating is is a proposed measure under *Commercial and Industrial Energy Efficient Construction*. Because this is a deemed savings measure the protocol will be exactly the same as previously stated in this document.

### **Programmable Thermostats**

This measure provides savings algorithms for programmable thermostats installed through the direct install program in commercial buildings. The baseline for this measure is manual thermostats that require occupant adjustment to change the space temperature. Non-communicating programmable thermostats achieve energy savings over manual thermostats by automatically setting temperatures back in the winter, or up in the summer, per a factory default schedule, or a user modified schedule. Setback/set up schedules achieve heating fuel savings in the winter, and cooling electric savings in the summer.

The savings factors for this measure come from the Michigan Energy Measures Database (MEMD), which shows deemed cooling and heating savings per 1,000 square feet of building space. The MEMD savings values for programmable thermostats were determined through measurement and verification of installed thermostats in a variety of commercial building types. For this measure, values for the Detroit airport locale are used because the ambient temperatures are closest to those for the New Jersey locale, and results are averaged across HVAC equipment types.

There are no peak demand savings for this measure, and motel and auto repair space types are excluded from this measure.

**Algorithms** 

Fuel Savings (MMBtu/yr) = SQFT<sub>1000</sub> \* SF<sub>heat</sub>

Energy Savings (kWh/yr) = SQFT<sub>1000</sub> \* SF<sub>cool</sub>

### **Definition of Variables**Service Measures

Energy efficient electric or natural gas cooking equipment of the following listed types utilized in commercial food service applications which have performance rated in accordance with the listed ASTM standards:

- Electric combination and convection ovens ASTM 1639 F
- Gas combination and convection ovens ASTM 1639 F
- Gas conveyor and rack ovens ASTM 1817 F
- Electric and gas small vat fryers ASTM 1361 F
- Electric and gas large vat fryers ASTM 2144-F
- Electric and gas steamers ASTM 1484-F

# Electric and Gas Convection Ovens, Gas Conveyor and Rack Ovens, Steamers, Fryers, and Griddles

The measurement of energy savings for these measures are based on algorithms with key variables provided by manufacturer data or prescribed herein.

#### **Algorithms**

Annual Energy Savings<u>SF<sub>heat</sub> = Heating savings factor (MMBtu per 1,000 ft<sup>2</sup> of building space)</u>

<u>SF<sub>cool</sub> = Cooling savings factor</u> (kWh or Therms) =  $D * (E_p + E_t + E_e)$ 

Demand Savings (kW) = kWh Savings / (D \* H)

Preheat Savings<sup>‡</sup>:  $E_p = P * (PE_b - PE_q)$ 

 $\frac{\text{Idle Savings}^{\ddagger}: E_{\mu} = (I_{b} - I_{q}) * ((H - (P^{*}P_{t})) - (I_{b}/PC_{b} - I_{q}/PC_{q}) * Lbs)}{(I_{b}/PC_{b} - I_{q}/PC_{q}) * Lbs}$ 

Cooking Savings:  $E_e = Lbs * Heat * (1/Eff_e - 1/Eff_e) / C$ 

**†** For gas equipment, convert these intermediate values to therms by dividing the result by 100,000 Btu/therm

Definition of Variables (See tables of values below for more information)

Savings algorithm, baseline values, assumed values and lifetimes developed from information on the Food Service Technology Center program's website, www.fishnick.com, by Fisher Nickel, Inc. and funded by California utility customers and		
administered by Pacific Gas and Electric Company under the auspices of the California Public Utility Commission.		
Occupancy Controlled Thermostats		
The program has received a large amount of custom electric applications for the installation of Occupancy Controlled Thermostats in hotels, motels, and, most recently, university dormitories. Due to the number of applications, consistent incentive amounts (\$75 per thermostat) and predictable savings of the technology TRC recommends that a prescriptive application be created for this technology.		
Standard practice today is thermostats which are manually controlled by occupants to regulate temperature within a facility. An occupancy controlled thermostat is a thermostat paired with a sensor and/or door detector to identify movement and determine if a room is occupied or unoccupied. If occupancy is sensed by the sensor, the thermostat goes into an occupied mode (i.e. programmed setpoint). If a pre programmed time frame elapses (i.e30 minutes) and no occupancy is sensed during that time, the		Formatted: Space Before: 6 pt, After: 6 pt
thermostat goes into an unoccupied mode (e.g., setback setpoint or off) until occupancy is sensed again. This type of thermostat is often used in hotels to conserve energy. The occupancy controlled thermostat reduces the consumption of electricity and/or gas by requiring less heating and/or cooling when a room or a facility is vacant or

#### **Dual Enthalpy Economizers**

Dual enthalpy economizers are used to control a ventilation system's outside air intake in order to reduce a facility's total cooling load. An economizer monitors the outside air to ensure that its temperature (sensible heat) and humidity (latent heat) are low enough to utilize outside air to provide cooling in place of the cooling system's compressor. This reduces the demand on the cooling system, lowering its usage hours, saving energy.

The measurement of energy savings associated with dual enthalpy economizers is based on algorithms with key variables provided through DOE 2 simulation modeling and ClimateQuest's economizer savings calculator. Savings are calculated per ton of connected cooling load. The baseline conditions are fixed damper for equipment under 5.4 tons and dry bulb economizer otherwise.

#### **Algorithms**

Energy Savings (kWh) = OTF \* SF \* Cap / Eff

### Demand Savings (kW) = Savings/Operating Hours

 Michigan Public Service Commission. 2017 Michigan Energy Measures Database (MEMD) with Weather Sensitive Weighting Tool. Available for download at: http://www.michigan.gov/mpsc/0,4639,7-159-52495\_55129----,00.html Formatted: Table Caption

### **Boiler Reset Controls**

The following algorithm detail savings for installation of boiler reset control on commercial boilers. Energy savings are realized through a better control on boiler water temperature. Through the use of software settings, boiler reset controls use outside or return water temperature to control boiler firing and in turn the boiler water temperature.

The input values are based on data supplied by the utilities and customer information on the application form, confirmed with manufacturer data. Unit savings are deemed based on study results.

### <u>Algorithms</u>

Fuel Savings (MMBtu/yr) = (% Savings) \* (EFLH<sub>h</sub> \* Cap<sub>in</sub>/hr) / 1,000 kBtu/MMBtu

### Definition of Variables

**OTF = Operational Testing Factor** 

SF = Approximate savings factor based on regional temperature bin data (assume 4576 for equipment under 5.4 tons where a fixed damper is assumed for the baseline and 3318 for larger equipment where a dry bulb economizer is assumed for the baseline). (Units for savings factor are in kWh x rated EER per ton of cooling or kWh\*EER/Ton)

Cap = Capacity of connected cooling load (tons)

Eff = Cooling equipment energy efficiency ratio (EER)

Operating Hours = 4,438 = Approximate number of economizer operating hours

### **Duel Enthalpy Economizers**

% Savings	= Estimated percentage reduction in heating load due to boiler reset			
-	controls (5%)			
EFLH <sub>h</sub>	= The Equivalent Full Load Hours of operation for the average unit			
during the heating season				
Cap <sub>in</sub>	<u>= Input capacity of qualifying unit in kBtu/hr</u>

#### **Dual Enthalpy Economizers**

Installation of Dual Enthalpy Economizers is a proposed measure under the Commercial and Industrial Energy Efficient Construction. Because there is no baseline assumption included in the protocols for this measure, the savings protocol will be exactly the same as previously stated in this document.

### Electronic Fuel-Use Economizers (Boilers, Furnaces, AC)

These devices are microprocessor-based fuel-saving controls for commercial HVAC. They optimize energy consumption by adjusting burner or compressor run patterns to match the system's load. They can be used to control gas or oil consumption for any type of boiler or forced air furnace system. There are also fuel use economizers available that control the electric consumption for commercial air conditioning and refrigeration units by optimizing compressor cycles to maximize energy efficiency.<sup>4</sup>Installation of variable Fuel Use Economizers is a proposed measure under the Commercial and Industrial Energy Efficient Construction. Because there is no baseline assumption included in the protocols for this measure, the savings protocol will be exactly the same as previously stated in this document.

### **Demand-Controlled Ventilation Using CO2 Sensors**

Maintaining acceptable air quality requires standard ventilation systems designers to determine ventilation rates based on maximum estimated occupancy levels and published CFM/occupant requirements. During low occupancy periods, this approach results in higher ventilation rates than are required to maintain acceptable levels of air quality. This excess ventilation air must be conditioned and therefore results in wasted energy.

Building occupants exhale  $CO_2$ , and the  $CO_2$  concentration in the air increases in proportion to the number of occupants. The  $CO_2$  concentration provides a good indicator of overall air quality. Demand control ventilation (DCV) systems monitor indoor air  $CO_2$ concentrations and use this data to automatically modulate dampers and regulate the amount of outdoor air that is supplied for ventilation. DCV is most suited for facilities where occupancy levels are known to fluctuate considerably.

A recent study of Fuel use economizer controls by the New York State Energy Research and Development Authority (NYSERDA) in conjunction with Brookhaven National Laboratories (BNL) found that the typical energy savings for these devices generally varies between 10.08% and 19.15%, when used under normal operating conditions and normalized for typical annual degree-days in the New York metro area.<sup>2</sup> The NYSERDA study tested at each of the different models of fuel use economizers manufactured by *Intellidyne, LLC*, (under the brand name *IntelliCon*). Operational data was recorded for various commercial heating, cooling, and refrigeration systems (of different sizes and fuel types) with and without the *IntelliCon* fuel use economizers added. The average energy savings across all system and fuel types and operational conditions was found to be 13%. Another study of *IntelliCon* fuel use economizers by Consolidated Edison, Inc. (ConEd) found a similar range of savings for the devices when the devices were studied as a control option for commercial refrigeration units at supermarkets in New York City and the surrounding area.<sup>3</sup>

Test results in both studies showed a very good payback for the devices across all applications studied. However, no discernable pattern was evident to determine which installations are most likely to yield the highest savings. Though actual savings will vary somewhat from project to project, it is reasonable to assume that program wide energy savings across all approved fuel use economizers measures will likely be close to the average savings found in the NYSERDA study. Annual energy savings for each approved fuel use economizer installation (for any *IntelliCon* brand or equivalent devices) can be estimated as simply 13% of the expected annual energy usage for the HVAC (or refrigeration) system without the device.

The magnitude of energy savings associated with DCV is a function of the type of facility, hours of operation, occupancy schedule, ambient air conditions, space temperature set points, and the heating and cooling system efficiencies. Typical values representing this factors were used to derive deemed savings factors per CFM of the

New Jersey's Clean Energy Program Protocols to Measure Resource Savings Formatted: Space After: 10 pt, Line spacing: Multiple 1.15 li, Allow hanging punctuation, Adjust space between Latin and Asian text, Adjust space between Asian text and numbers, Font Alignment: Auto design ventilation rate for various space types. These deemed savings factors are utilized in the following algorithms to predict site specific savings.

Electric Energy Savings (kWh) = (AEU \* 0.13)/yr) = CESF \* CFM

Peak Demand Savings (kW) = CDSF \* CFM

Fuel Savings (MMBtu) = (AFU \* 0.13)/yr) = HSF \* CFM

Definition of Variables

AFU = Annual Fuel Usage for an uncontrolled (gas, oil, propane) HVAC unit (MMBtu or gallons)

<u>CESF = Cooling</u>Sources:

## **Demand Control Ventilation Using CO2 Sensors**

Demand control ventilation (DCV) monitors indoor air CO<sub>2</sub> content as a result of occupancy production levels and uses this data to regulate the amount of outdoor air that is permitted for ventilation. In order to ensure adequate air quality, standard ventilation systems permit outside air based on estimated occupancy levels in CFM/occupant. However, during low occupancy hours, the space may become over ventilated due to decreased CO<sub>2</sub> levels. This air must be conditioned and, therefore, unnecessary ventilation results in wasted energy. DCV reduces unnecessary outdoor air intake by

The measurement of energy savings associated with DCV is based on hours of operation, occupancy schedule, return air enthalpy, return air dry bulb temperature, system air flow, outside air reduction, cooling system efficiency, and other factors. As a conservative simplification of complex algorithms, DCV is assumed to save 5% of total facility HVAC load in appropriate building types based on FEMP DCV documentation.

## **Pipe Insulation**

Un-insulated hot water carrying pipes lose considerable heat to outside air due to high thermal conductivity.- In order to reduce this heat loss, pipes can be covered with a layer of fiberglass insulation, which will reduce source heating demand, resulting in significant energy savings.

The measurement of energy savings associated with pipe insulation is based on the length of the supply pipe, pipe diameter, relative thermal conductivity of bare and insulated piping and the temperature difference between supplied water and outside air temperature as indicated in the EPRI report referenced below. The baseline case is un insulated copper pipe and the default proposed case is 0.5" of fiberglass insulation.

#### Algorithms

Energy Savings (kWh) =  $(L * (HLC_{base} - HLC_{ee}) / C) * \Delta T * 8,760$ 

Formatted: Underline

**Definition of Variables** 

L = Length of pipe from water heating source to hot water application (ft)

HLC<sub>base</sub> = Pipe heat loss coefficient by pipe diameter (baseline) (BtuH -°F-ft)

<u>HLC<sub>ee</sub> = Pipe heat loss coefficient by pipe diameter (proposed) (BtuH  $^{\circ}F$  ft) C = Conversion from Btu to kWh or Therms (3,413 for kWh (Electric Water Heating), 100,000 for Therms (Gas Water Heating)</u>

 $\Delta T$  = Average temperature difference between supplied water and outside air temperature (°F)

8,760 = Hours per year

## **Pipe Insulation**

This measure applies to insulation installed on previously bare hot water distribution piping located in unconditioned spaces. Deemed savings factors were derived using the North American Insulation Manufacturers Association, 3E Plus Version 4.1 heat loss calculation tool. The savings factors represent average values for copper or steel pipe with mineral fiber or polyolefin tube pipe insulation. Savings are a function of pipe size and insulation thickness. A table of savings factors for nominal pipe size ranging from <sup>1</sup>/<sub>2</sub> inch to 4 inches, with insulation ranging from <sup>1</sup>/<sub>2</sub> inch to 2 inches thick is provided.

The savings factors are based on a fluid temperature of 180°F, and an ambient temperature of 50°F, resulting in a temperature differential of 130°F. If the actual temperature differential varies significantly from this value, the reported savings should be scaled proportionally.

The default value for annual operating hours represents the average annual hours when space heating is required. For non-space heating applications, the value should be adjusted to reflect the annual hours when the hot fluid is circulated.

<u>Algorithms</u>

Fossil Fuel Source:

Fuel Savings (MMBtu/yr) = SF \* L \* Oper Hrs / EFF

Electric Source:

Energy Savings (kWh/yr) = SF \* L \* Oper Hrs / EFF / C

<u>Scaling</u>: Only applicable if differential between the fluid temperature and space temperature is significantly different than 130°F. If this is the case, the fuel or electric savings calculated with the above formulas should be multiplied by the resulting scaling factor deroived as:

Scaling Factor (unitless) = (FT - ST)/130

<u>Fuel or electric savings calculated using the derived savings factors should be multiplied</u> by the acaling factor.

Scaled Savings (MMBtu/year or kWh/yr) = Calculated Savings \* Savings Factor

**Definition of Variables** 

<u>SF</u> = Savings factor derived from #E Plus Version 4.1 tool, Btu/hr-ft see table below

<u>L</u> = Length of pipe from water heating source to hot water application, ft Oper Hrs = hours per year fluid flows in pipe, hours

Formatted: Heading 4, Space After: 6 pt

# Lighting and Lighting Controls

For lighting and lighting control projects performed by Direct Install programs, use the C&I prescriptive lighting tables for the lighting types identified within those tables. For any fixtures not listed on the table, go to the source table for that fixture. If the fixture is not on the source table, then use manufacture cut sheets for replacement kW to calculate the savings.

Eligible measures include:

Prescriptive Lighting T8 T5 CFL Screw-In LED Screw-In LED Linear Tubes LED Hard-Wired Fixtures Lighting Controls

Occupancy Sensors High-Bay Occupancy Sensors Photocell with Dimmable Ballast Formatted: Page break before

**Formatted:** Space Before: 6 pt, After: 6 pt

# **C&I Large Energy Users Incentive Program**

The purpose of the program is to foster self-investment in energy-efficiency, and combined heat and power projects while providing necessary financial support to large commercial and industrial utility customers in New Jersey.

## Protocols

Please refer to the Pay for Performance Existing Buildings protocols to calculate demand and energy savings for the Large Energy Users Program. -If a project addresses a specific end-use technology, protocols for that technology should be used.

# **C&I Customer-Tailored Energy Efficiency Pilot Program**

The purpose of the program is to better serve the needs of specific commercial and industrial customers whose usage is too large for them to qualify for the Direct Install program, but too low for the Large Energy Users Program.

## Protocols

Please refer to the Pay for Performance Existing Buildings protocols to calculate demand and energy savings for the Large Energy Userscomprehensive projects in the Customer <u>Tailored Pilot</u> Program.- If a project addresses a specific end-use technology, protocols for that technology should be used. Formatted: Indent: Left: 0"

Formatted: Indent: Left: 0"

# **Renewable Energy Program Protocols**

# **SREC Registration Program (SRP)**

The energy and demand impacts for customer sited solar PV generation systems participating in the program are based on fixed assumptions which are applied to the total project system capacity. The annual electricity generation is derived by multiplying the estimated annual production factor of 1,200 kWh per kW by the total system capacity (kW) to yield the estimated annual output (kWh).<sup>70</sup> The combined values for all projects participating in a specified period are then summed up and converted to MWh for reporting purposes.

## **Renewable Non-SRP**

## **Renewable Electric Storage**

The impact of Renewable Electric Storage, if any on net renewable energy generation will be analyzed over the coming year based upon quarterly performance reporting that is required of participants in this program.

1

<sup>&</sup>lt;sup>70</sup> Estimated annual production factor is based on combined average calculation of the PV Watts estimated annual output for the Newark and Atlantic City weather stations.

# Appendix A Measure Lives

# NEW JERSEY STATEWIDE ENERGY-EFFICIENCY PROGRAMS Measure Lives Used in Cost-Effectiveness Screening April 2012

If actual measure lives are available through nameplate information or other manufacturing specifications with proper documentation, those measure lives should be utilized to calculate lifetime savings.- In the absence of the actual measure life, Protocol measure lives <u>listed below</u> should be utilized. <u>Measure life values listed below are from</u> the California Database of Energy Efficient Resources<sup>71</sup> (DEER) unless otherwise noted.
